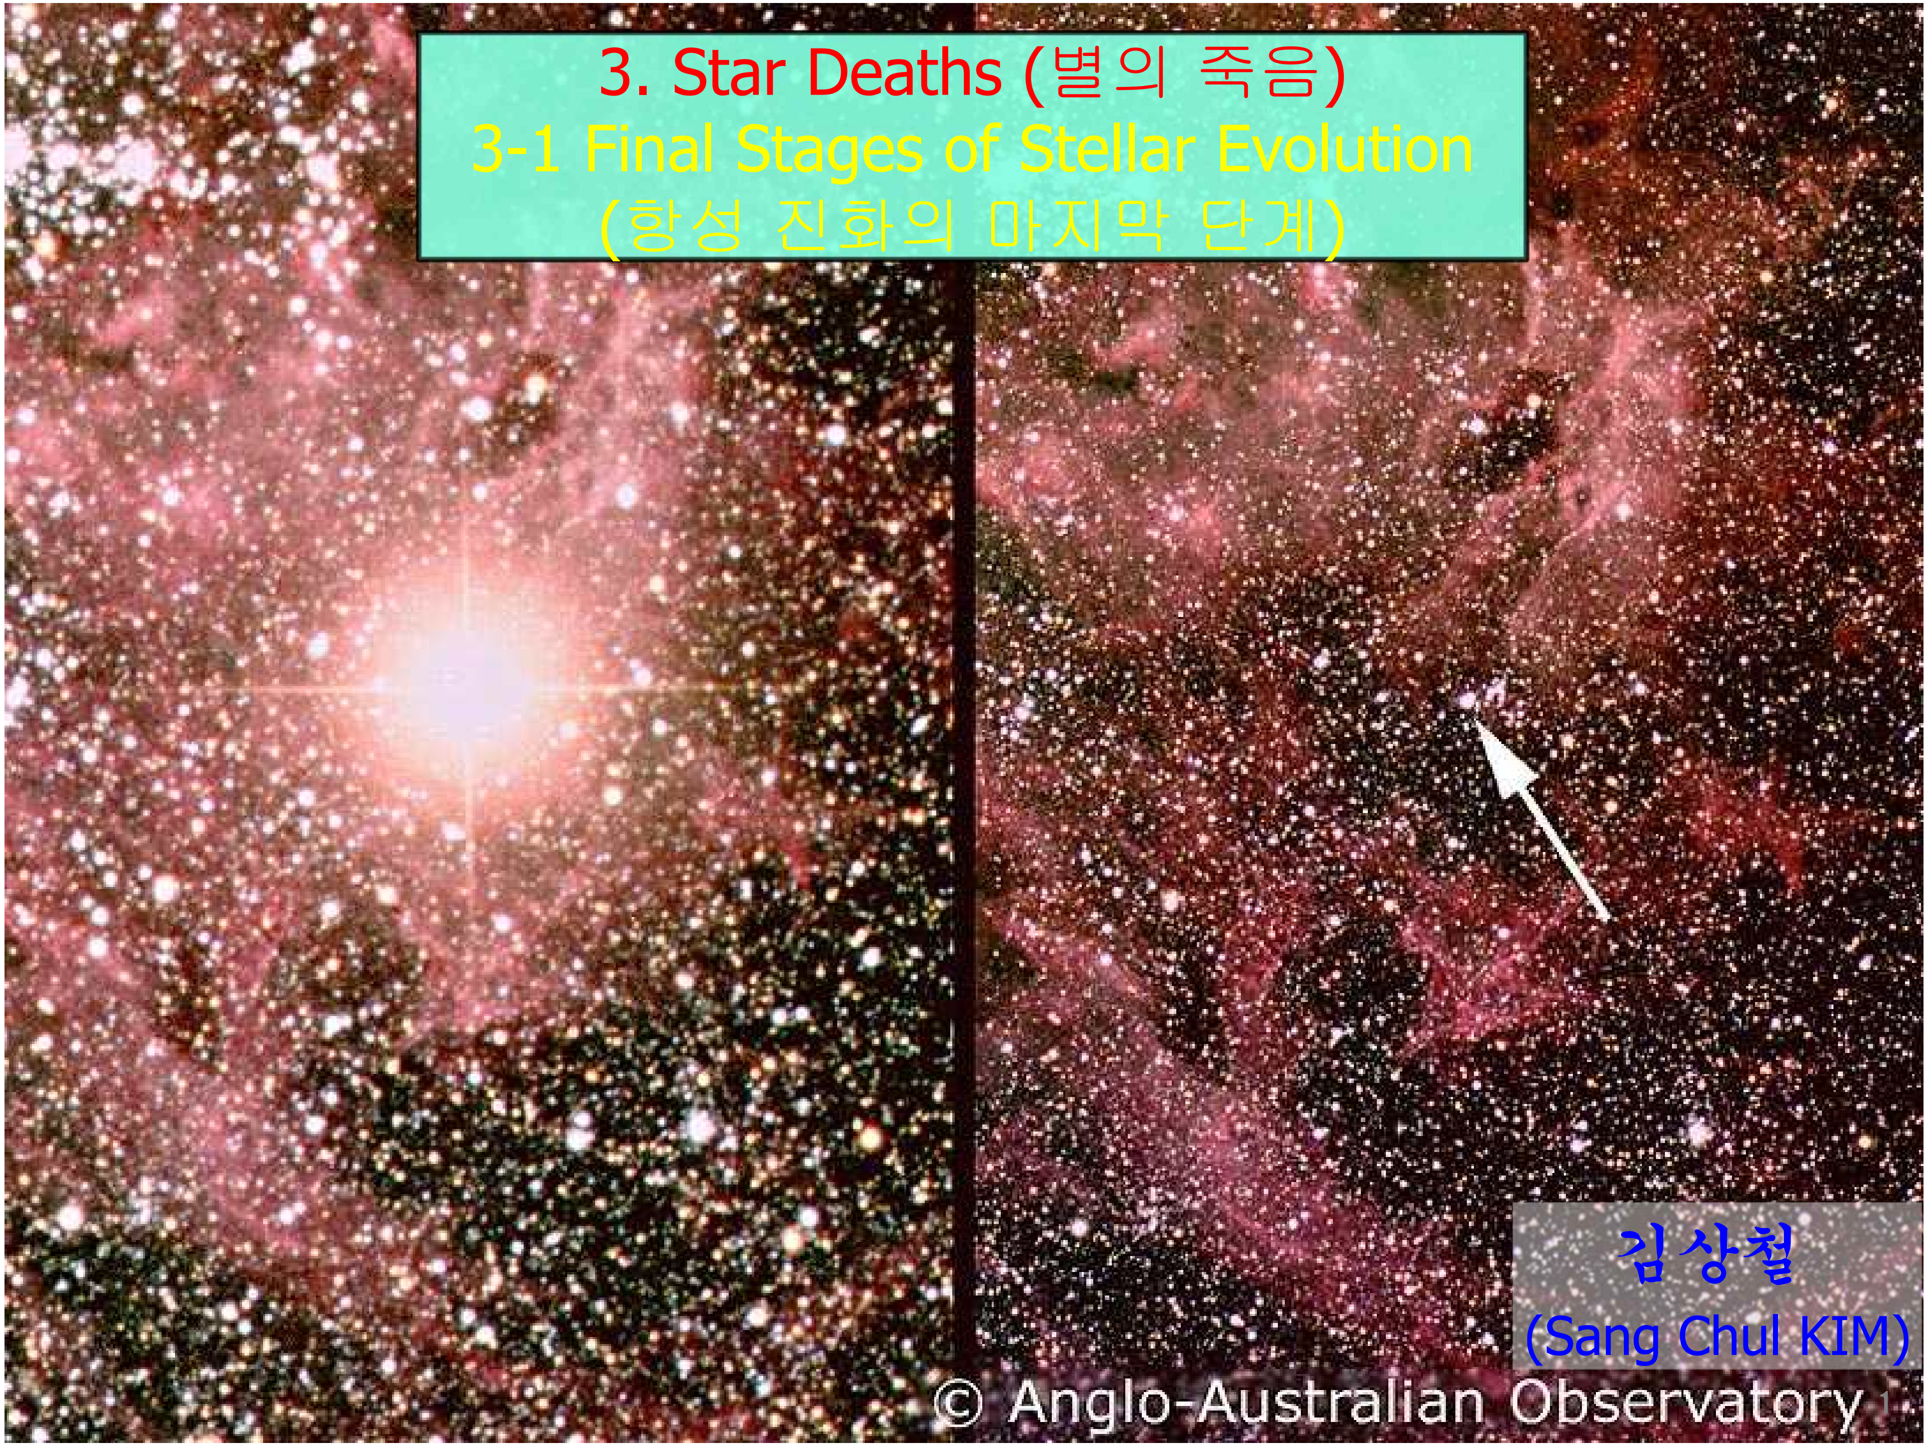
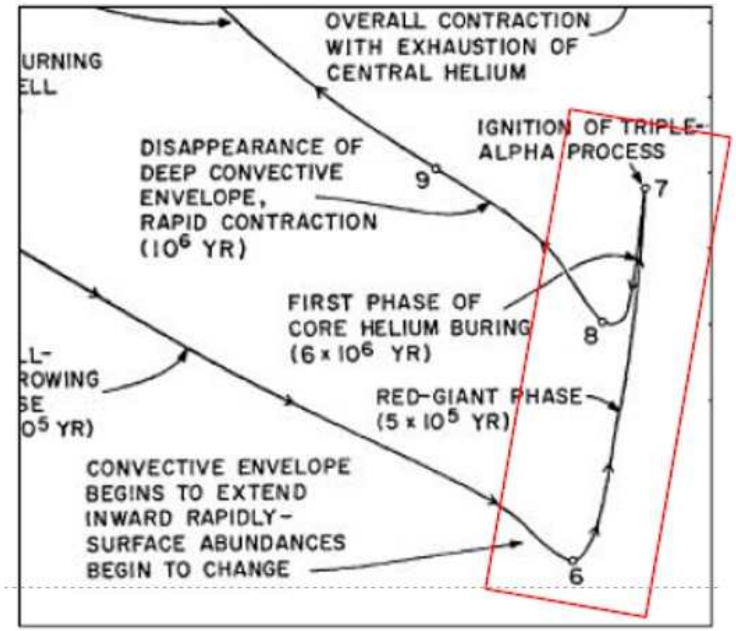
3. Star Deaths (별의 죽음)

3-1 Final Stages of Stellar Evolution
(항성 진화의 마지막 단계)



김상철
(Sang Chul KIM)

5 $M_\odot$ star evolution after ignition of the triple-α process



- At point 7 :
- $T_c = 1.3\times10^8$ K, ρ_c=7700 g/cm^3
- High central T and ρ
  → triple-α process begins

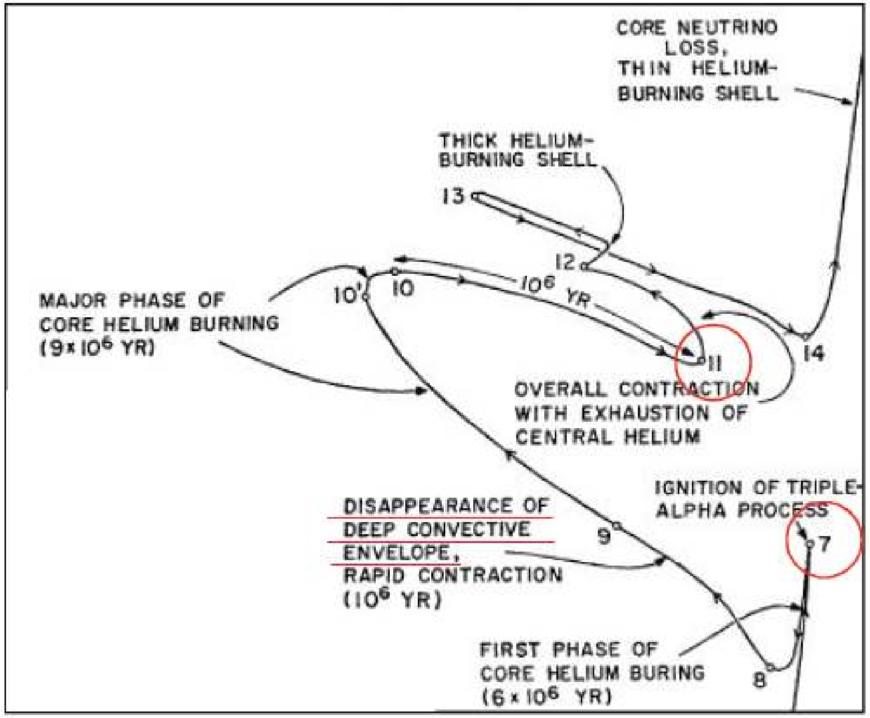
- Strong T-dependence

$$\epsilon_{3\alpha} \simeq \epsilon'_{0,3\alpha}\rho^2 Y^3 f_{3\alpha} T_8^{41.0}$$

- ($7\rightarrow8$)
- New E source in core → core expands, cools → shell E-output ↓ → L↓
- Envelope contracts → T_{eff} ↑

- ($8\rightarrow10$)
- Since envelope contraction → H-b shell compresses → shell E-output↑ → L↑

Horizontal Branch (HB) Stars



7-11 : generally horizontal evolution
"Horizontal branch (HB)"

He-b core + H-b shell

(variables=open circles)

Galactic Astronomy (J. Binney & M. Merrifield, 1998) p. 334

Pulsating Variable Stars

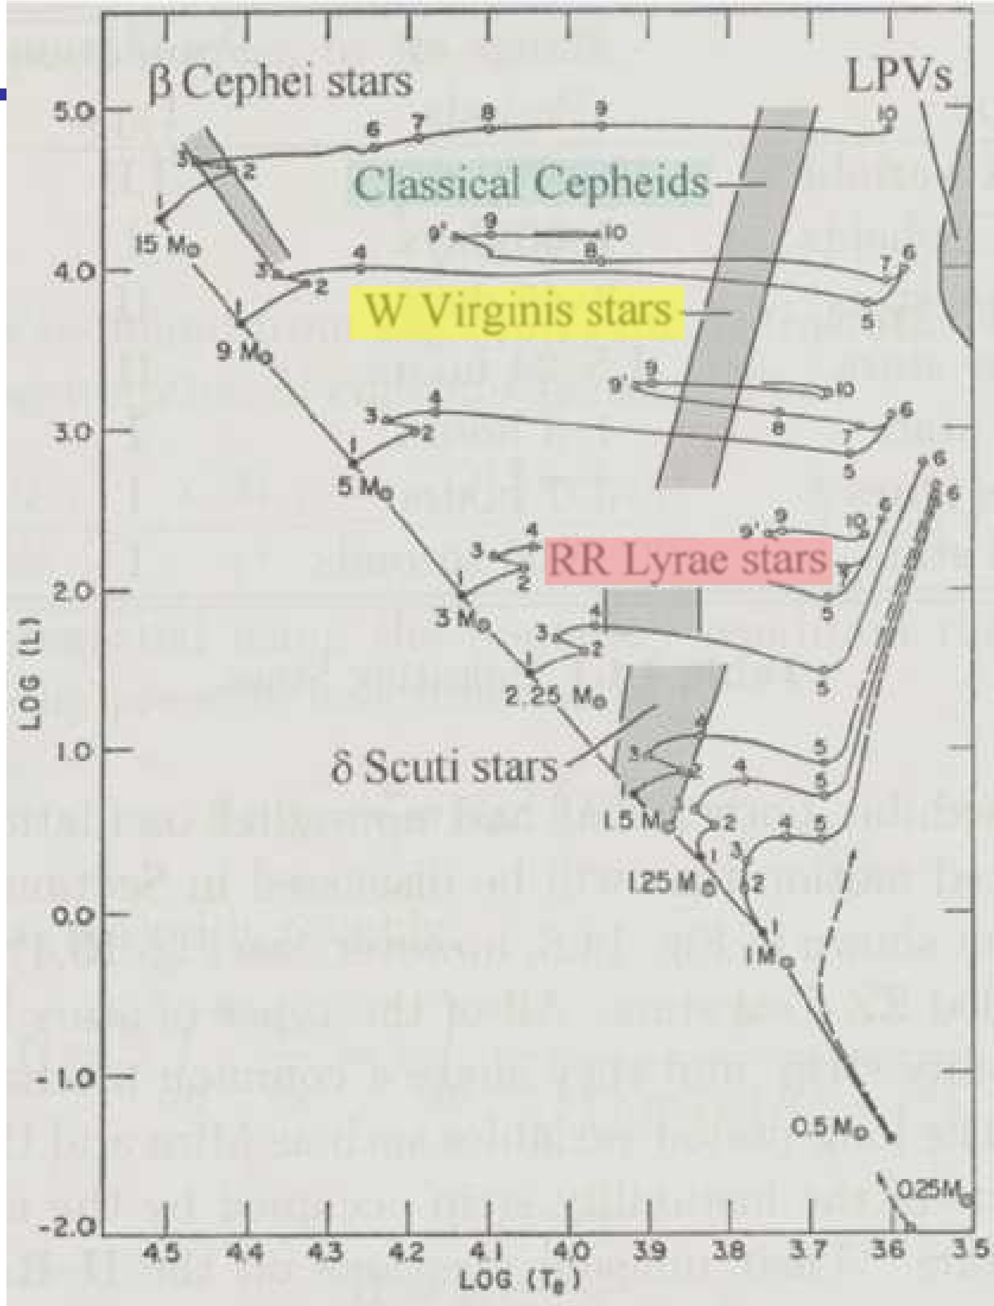
HB stars in the instability strip (IS) = RR Lyrae stars
→Instabilities in outer envelope
→Periodic pulsations
→Variations in L, T, R, surface radial vel.

Instability strip
: narrow (~600 – 1000K wide)

Stars evolve horizontally along the IS
→Enters : starts pulsating
→Leaves : cease pulsating

Type	Periods	Population	Comments
Classical Cepheids	1-50 days	I	Radial Pulsation
W Virginis stars (Pop II Cep)	2-45 days	II	Radial Pulsation
RR Lyrae stars	1.5 – 24 hours	II	Radial Pulsation

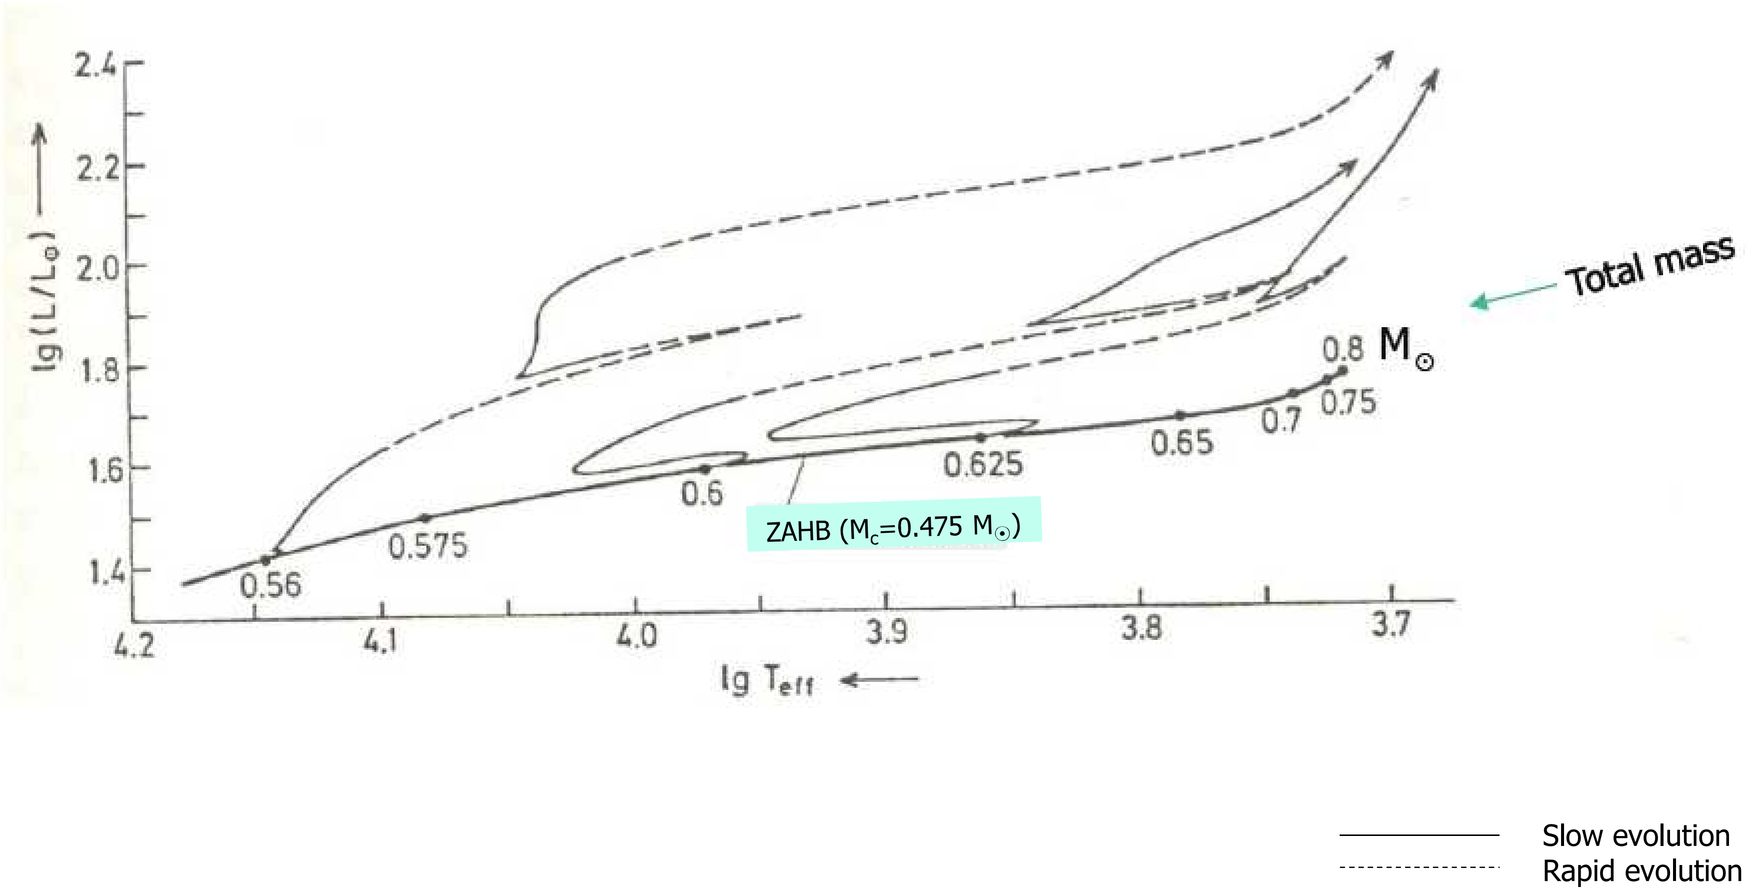
These stars are distance indicators !



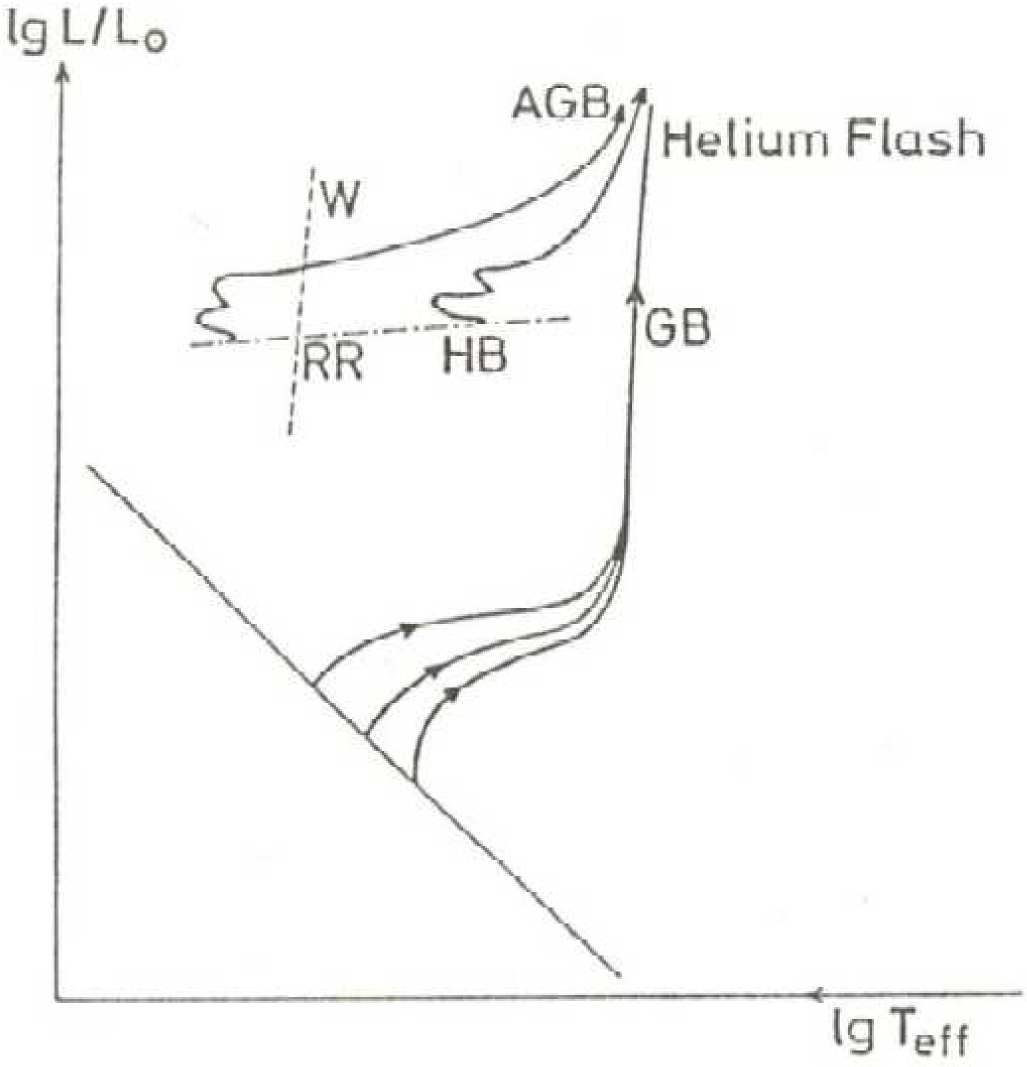
An Introduction to Modern Astrophysics (2nd edition),
Bradley W. Carroll & Dale A. Ostlie (1996), p. 547

Post-HB Evolution – in HR diagram

Zero-age HB (ZAHB) and evolution afterwards
(He-core M_c =0.475 $M_\odot$, H-rich envelope with X=0.699, Y=0.3)



Post-HB Evolution – in HR diagram



- Evolution of low-mass stars, with three different masses

(RR = RR Lyrae stars)

(W = W Virginis stars)

Stellar Structure and Evolution, R. Kippenhahn and A. Weigert (1990) p. 323 – Fig. 32.10

RR Lyrae stars

- Periodic variable stars
- P = 1.5 to 24 h (~12 h), Peak M_V ~ 0-1 mag, spectra A2 to F6
- Current mass ~ 0.8 $M_\odot$ (original MS mass ~ 1 $M_\odot$), old, relatively metal-poor
- In GCs and in low-metallicity systems (population II) – But, some have high metallicity

$M_V(RR) = +0.71 \pm 0.12$ at $\langle[\mathrm{Fe/H}]\rangle = -1.61$ for the halo (162 stars)

$M_V(RR) = +0.79 \pm 0.30$ at $\langle[\mathrm{Fe/H}]\rangle = -0.76$ for the thick disk (51 stars)

Layden et al. (1996, AJ, 112, 2110)

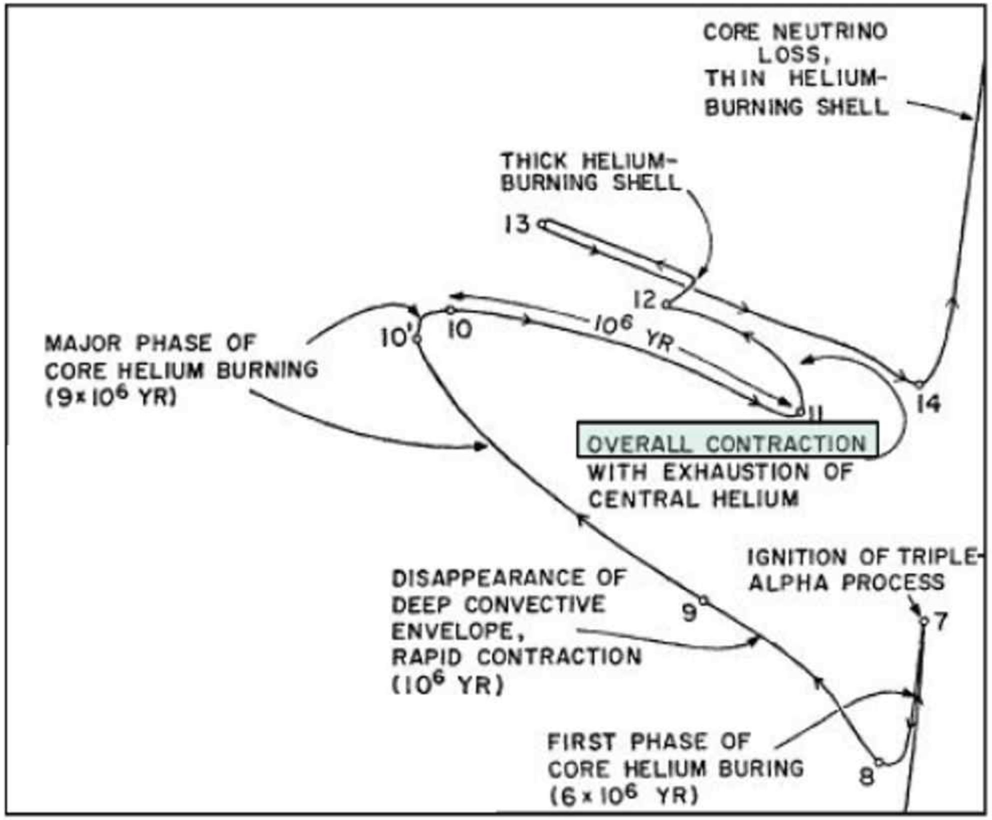
$$\langle M_V \rangle = (0.16 \pm 0.03)[\mathrm{Fe/H}] + 1.02 \pm 0.03 \quad (5.24)$$

$$\langle M_K \rangle = -(2.3 \pm 0.2)\log(P/1\,\mathrm{d}) - 0.88 \pm 0.06 \quad (5.25)$$

$$\langle M_K \rangle = -(2.0 \pm 0.3)\log(P/1\,\mathrm{d}) + (0.06 \pm 0.04)[\mathrm{Fe/H}] - 0.7 \pm 0.1 \quad (5.26)$$

Galactic Astronomy (James Binney and Michael Merrifield, 1998) p. 296

Post-HB, early-AGB (E-AGB)

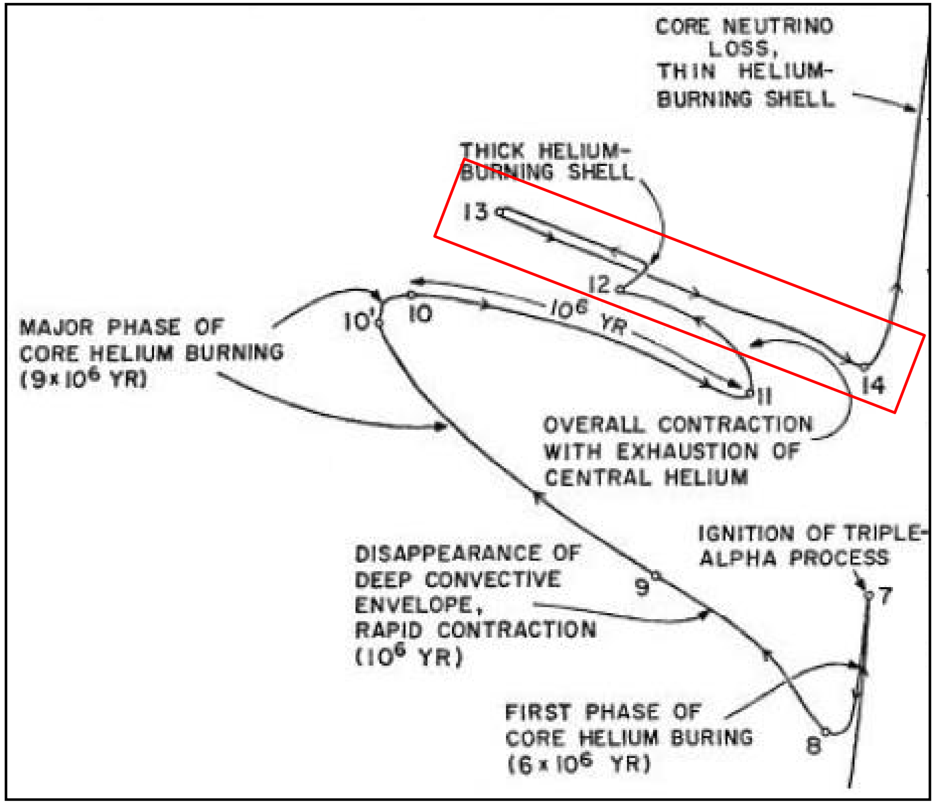


- At point 11 : core He exhausted
  → entire star contracts
  → core T ↑

- During 11 → 12
  : thick He-b shell develops

Asymptotic Giant Branch (AGB) stars

Early-AGB (E-AGB)



After point 12

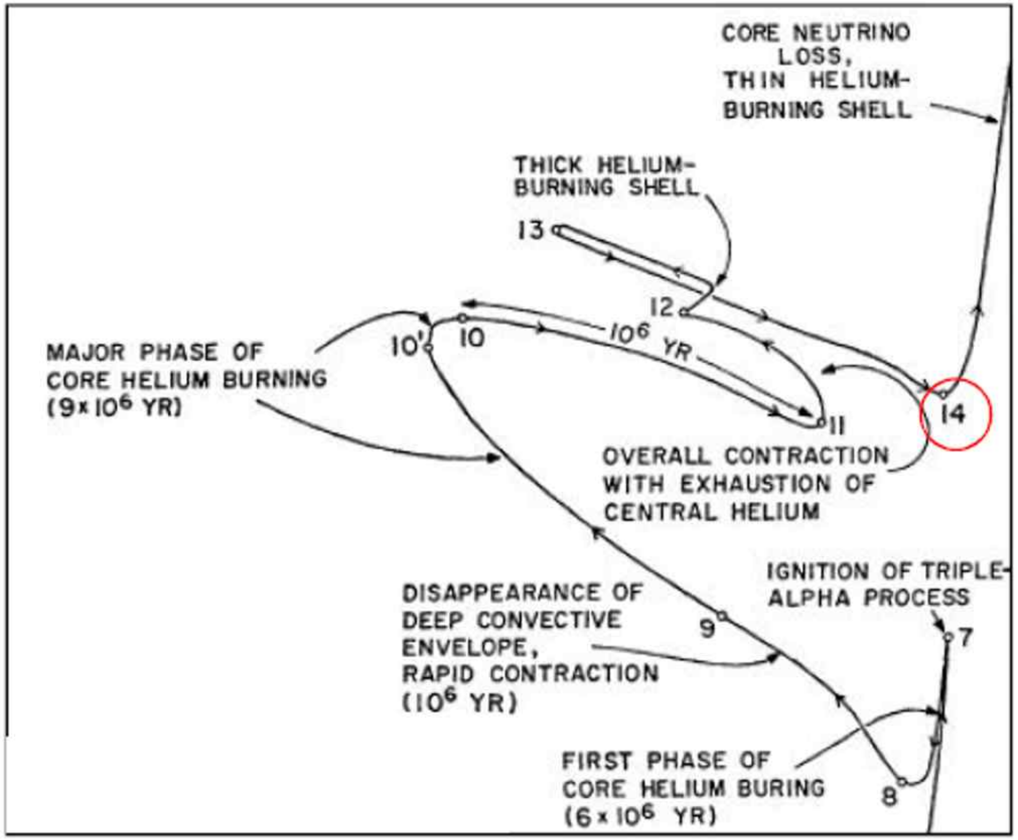
- He-b shell produces more E
- Envelope expands + cools

- T_{eff} ↓ → convective envelope deepens again (extending downward to the chemical discontinuity between the H-rich outer layers and the He-rich region above the He-b shell)

→ Mixing = **second dredge-up**

→ Increases He-, N-content of the envelope

Early-AGB (E-AGB)



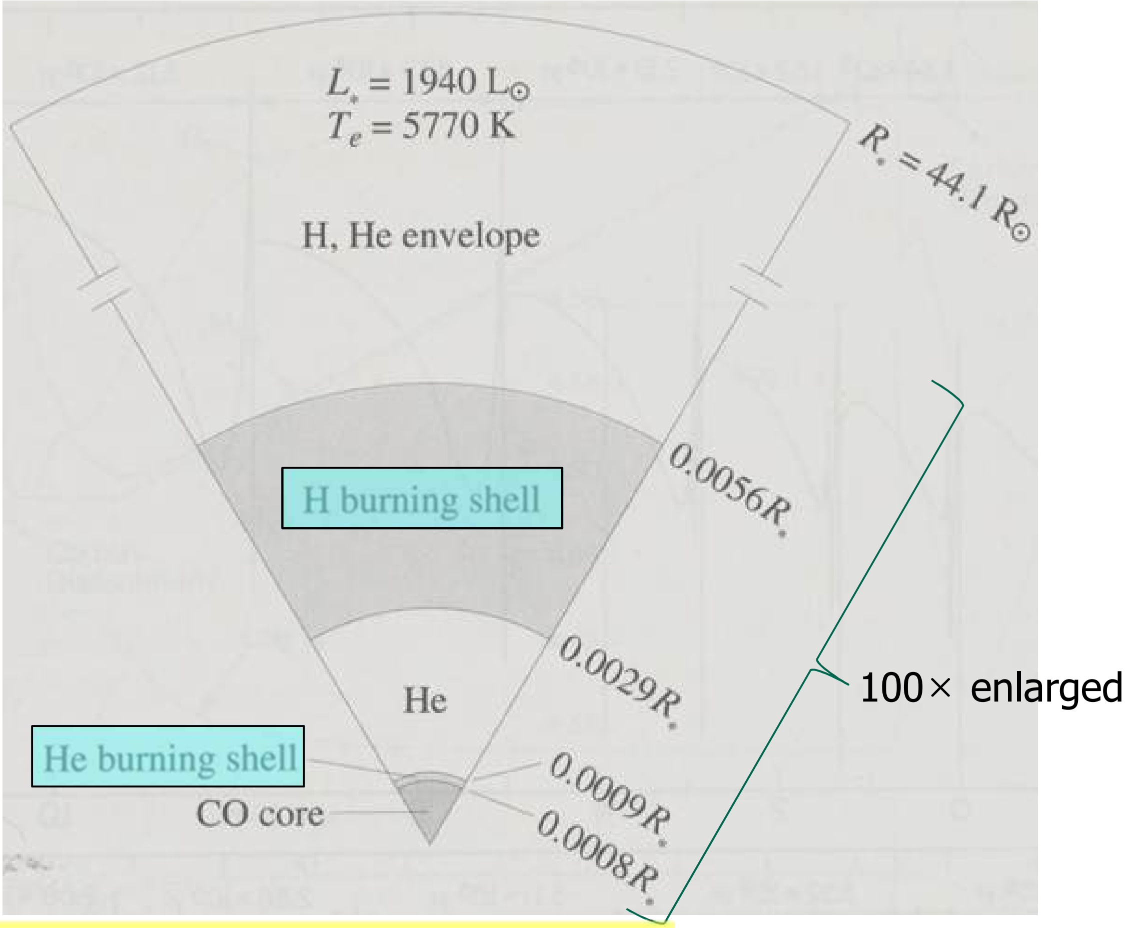
At point 14 :

$T_c \sim 2\times10^8$ K, $\rho_c \sim 10^6$ g/cm^3

Interior structure →

5 $M_\odot$ star - AGB (asymptotic giant branch)

Inert CO core +
Two shell sources
(not to scale)



H shell burning : begins to turn-on and -off periodically

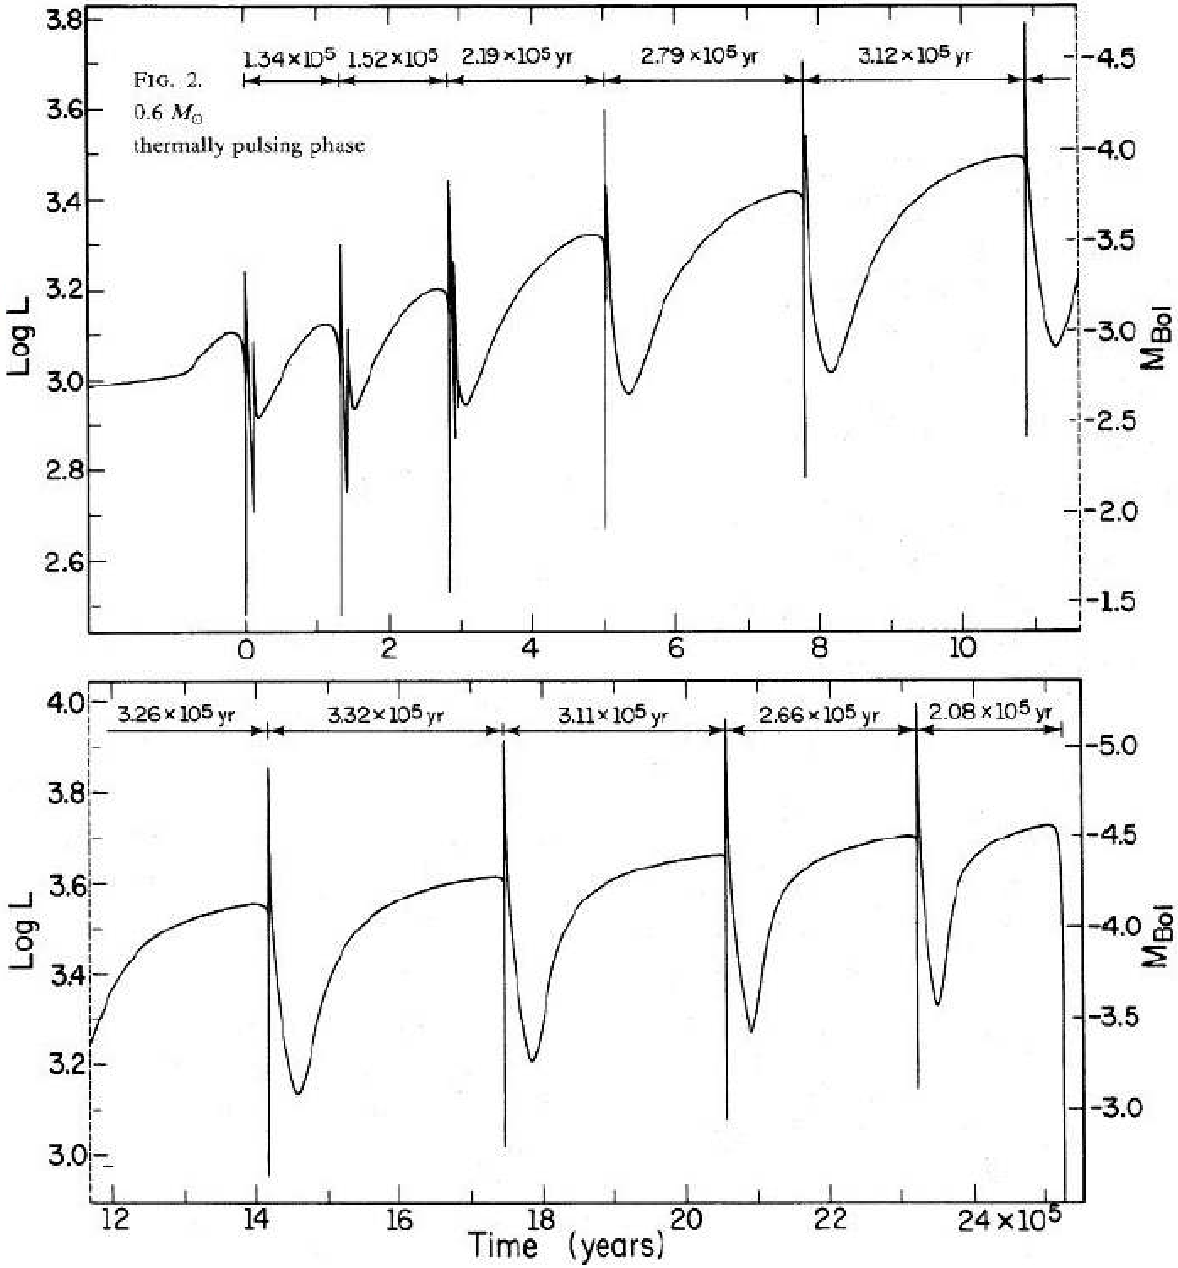
H-b shell dumps He onto the He-layer → He-layer mass↑, becomes slightly degenerate
→ He-layer T↑ → He-shell flash (~core He flash of low-mass stars, but much less energetic)
→ Drives H-b shell outward → cool, turn-off for a time

He-shell burning diminishes → contract, T↑ → H-shell burning recovers → repeats → **thermally pulsing AGB**

An Introduction to Modern Astrophysics (2nd edition), Bradley W. Carroll & Dale A. Ostlie (1996), p. 501

Thermally pulsing AGB (TPAGB)

- 0.6 $M_\odot$
- Pulse period = f(stellar mass)
  : from 10^3 years (~5 $M_\odot$)
  to 10^5 years (~0.6 $M_\odot$)
- Pulse amplitude grows w/successive event



Iben 1982 (ApJ, 260, 821 –
Low mass AGB evolution. I.) – Fig. 2

AGB stars

- AGB stars – strong wind + rapid mass-loss $\dot{M} \sim 10^{-4} M_\odot \ yr^{-1}$ "superwind"

Cool (effective T ~3,000 K)

→ dust grains exist in the matter expelled

- O-rich environment → Silicate grains form
- C-rich environment → Graphite grains form

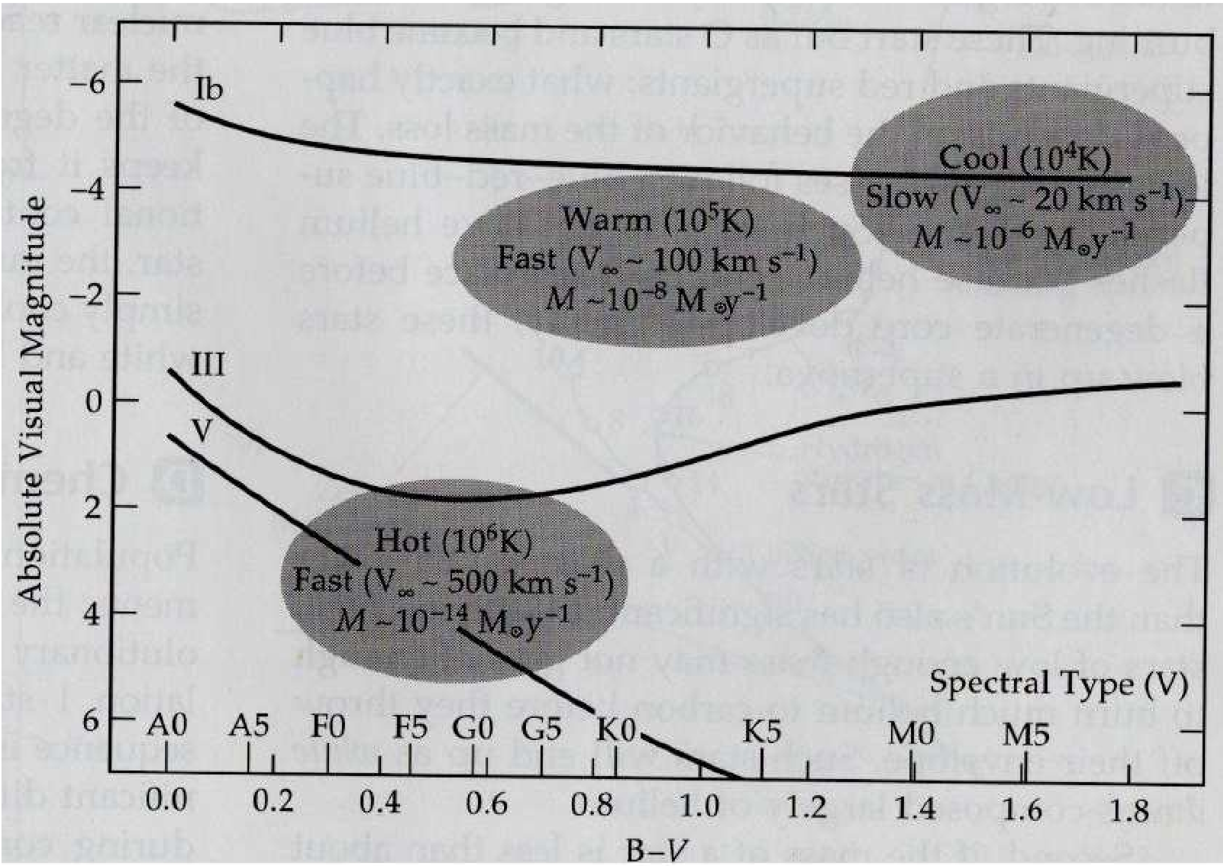
- Stellar initial masses evolving to AGB : $0.89 \leq M/M_\odot \leq 5.0$

(Vassiliadis & Wood 1993, ApJ, 413, 641 : Evolution of low- and intermediate-mass stars to the end of the AGB with mass loss)

- Evolution afterwards
  - depends on initial mass and mass-loss
  - massive stars – burnings up to form Fe → neutron stars (NSs), black holes (BHs)
  - low-mass stars – white dwarfs (WDs) + planetary nebulae (PNe)
  - dividing mass ~ $8 M_\odot$

Mass Loss Rates

- Solar mass loss rate (via wind) : $10^{-14}\ M_{\odot}/yr$
- RGB and supergiants, massive O-type stars : $10^{-7} \sim 10^{-6}\ M_{\odot}/yr$



Introductory Astronomy and Astrophysics (4th edition)
Michael Zeilik & Stephen A. Gregory (1998), p. 323

Thermonuclear Energy Generation Stages

Process	Fuel	Major products	Temperature (K)	Minimum mass ($M_\odot$)
H-burning	H	He	$1\text{-}3\times10^7$	0.1
He-burning	He	$^{12}_{6}C$, $^{16}_{8}O$	2×10^8	1
C-burning	C	$^{16}_{8}O$, $^{20}_{10}Ne$, $^{23}_{11}Na$, $^{23}_{12}Mg$, $^{24}_{23}Mg$	8×10^8	1.4
Ne-burning	Ne	$^{16}_{8}O$, Mg	1.5×10^9	5
O-burning	O	$^{24}_{12}Mg$, $^{27}_{13}Al$, $^{28}_{14}Si$, $^{31}_{15}P$, $^{32}_{16}S$	2×10^9	10
Si-burning	Mg to S	near Fe	3×10^9	20

Introductory Astronomy and Astrophysics (4th edition)
Michael Zeilik & Stephen A. Gregory (1998), p. 328

Thermonuclear Energy Generation Stages

Table 1 Evolution of a 15-solar-mass star.

Stage	Timescale	Fuel or product	Ash or product	Temperature (10^9 K)	Density (gm cm^{-3})	Luminosity (solar units)	Neutrino losses (solar units)
Hydrogen	11 Myr	H	He	0.035	5.8	28,000	1,800
Helium	2.0 Myr	He	C, O	0.18	1,390	44,000	1,900
Carbon	2000 yr	C	Ne, Mg	0.81	2.8×10^5	72,000	3.7×10^5
Neon	0.7 yr	Ne	O, Mg	1.6	1.2×10^7	75,000	1.4×10^8
Oxygen	2.6 yr	O, Mg	Si, S, Ar, Ca	1.9	8.8×10^6	75,000	9.1×10^8
Silicon	18 d	Si, S, Ar, Ca	Fe, Ni, Cr, Ti, ...	3.3	4.8×10^7	75,000	1.3×10^{11}
Iron core collapse*	$\sim$1 s	Fe, Ni, Cr, Ti, ...	Neutron star	>7.1	$>7.3 \times 10^9$	75,000	$>3.6 \times 10^{15}$

* The pre-supernova star is defined by the time at which the contraction speed anywhere in the iron core reaches 1,000 km s^{-1}.

Woosley & Janka 2005 Nature Physics, 1, 147

Stellar lifetimes

Table 1 Stellar lifetimes[a] for a selection of solar-metallicity ($Z = 0.014$) models (using models from Karakas 2014)

Mass/$M_\odot$	Main sequence	RGB	Core He burning	AGB	Total[b]
1.0	9685	2360	118.3	21.35	12,186
2.0	874.5	162.3	130.9	18.21	1185.9
5.0	80.03	3.053	23.07	1.997	108.15
8.0	29.12	0.484	6.475	0.435	36.519

[a]Lifetimes are in Myr (10^6 years)
[b]The total stellar lifetimes includes all nuclear burning phases but does not include the post-AGB or white dwarf cooling phases

A. I. Karakas 2017, Handbook of Supernovae, Volume 1, p. 461

Evolving up the AGB (asymptotic giant branch)

- Early-AGB (E-AGB) : He shell burning
  Radius increases (up to 1 AU ~215 $R_{\odot}$)

- Thermally pulsing AGB (TP-AGB) : when He shell runs out of fuel
  H shell burning
  When He builds up → He-shell ignites explosively (He-shell flash)

- He-b shell converts more and more of the He into C and then into O
  → CO core mass ↑/ core contracts slowly, ρ_c↑
  → electron degeneracy pressure begins to dominate

- Similar to the development of an electron-degenerate He-core
  in a low-mass star
  during its rise up the RGB

Massive ($M \geq 8\ M_\odot$) star evolution

- He-b shell → add ash to the CO core
- CO core continues to contract
- ${}^{12}_{6}C$-burning starts
- By-products : ${}^{16}_{8}O$, ${}^{20}_{10}Ne$, ${}^{23}_{11}Na$, ${}^{23}_{12}Mg$, ${}^{24}_{12}Mg$

- NeO core
- ${}^{16}_{8}O$-burning starts

→ Making ${}^{28}_{14}Si$-dominated (and ${}^{32}_{16}S$) core

---

At $T \sim 3 \times 10^9$ K → Si-burning starts

Making iron(${}^{56}_{26}Fe$)-peak elements, like ${}^{54}_{26}Fe$, ${}^{56}_{26}Fe$, ${}^{56}_{28}Fe$, and finally iron-core

$50 \leq A \leq 62$

CC SNe vs. SNe Ia

- CC SNe : not in early-type galaxies, Spiral galaxies – spiral arms
- SN Ia : all types of galaxies (Spiral galaxies – no spatial preference)

- spiral arms = short-lived massive stars

→ CC SNe = massive stars

SN Ia = not that massive stars

- Total energy emitted in neutrinos 3×10^{53} erg
- Total kinetic energy $\sim 10^{51}$ erg = f.o.e. = foe

$\sim$1% of total kinetic energy comes in photons $\sim 10^{49}$ erg

(peak luminosity $\sim 10^{43}$ erg/s, $\sim 10^{9}\ L_{\odot}$, ~brightness of an entire galaxy)

CC SNe vs. SNe Ia

- Total energy emitted in neutrinos 3×10^{53} erg
- Total kinetic energy $\sim 10^{51}$ erg = f.o.e. = foe

$\sim$1% of total kinetic energy comes in photons $\sim 10^{49}$ erg
(peak luminosity $\sim 10^{43}$ erg/s, $\sim 10^{9}\ L_{\odot}$, ~brightness of an entire galaxy)

foe 미국식 [ˈfoʊ] 영국식

명사 an enemy

foe 미국식 [foʊ] 영국식 [fəʊ]

https://endic.naver.com/

[명사] (구식 또는 격식) 적(敵)

적² 敵

(원수) (the) enemy, (literary) **foe**

원수¹ 怨讐

(적)enemy, (literary) **foe**

3. Star Deaths (별의 죽음)
3-3 White Dwarfs, Neutron Stars, and Black Holes (백색왜성, 중성자별, 검은구멍)

Helix Nebula in the Aquarius

https://www.dailymail.co.uk/sciencetech/article-3517714/The-dying-star-rewrite-know-stellar-evolution-White-dwarf-bizarre-atmosphere-oxygen.html

https://www.nasa.gov/audience/forstudents/5-8/features/nasa-knows/what-is-a-supernova.html

1. Planetary nebula evolution in the CMD

- M = 0.6 $M_\odot$
- CO-core
- Initial composition : X=0.749, Y=0.25, Z=0.001

- (amount of mass remaining in the H-rich envelope, $M_\odot$)

- After '11', loses last remnants of envelope

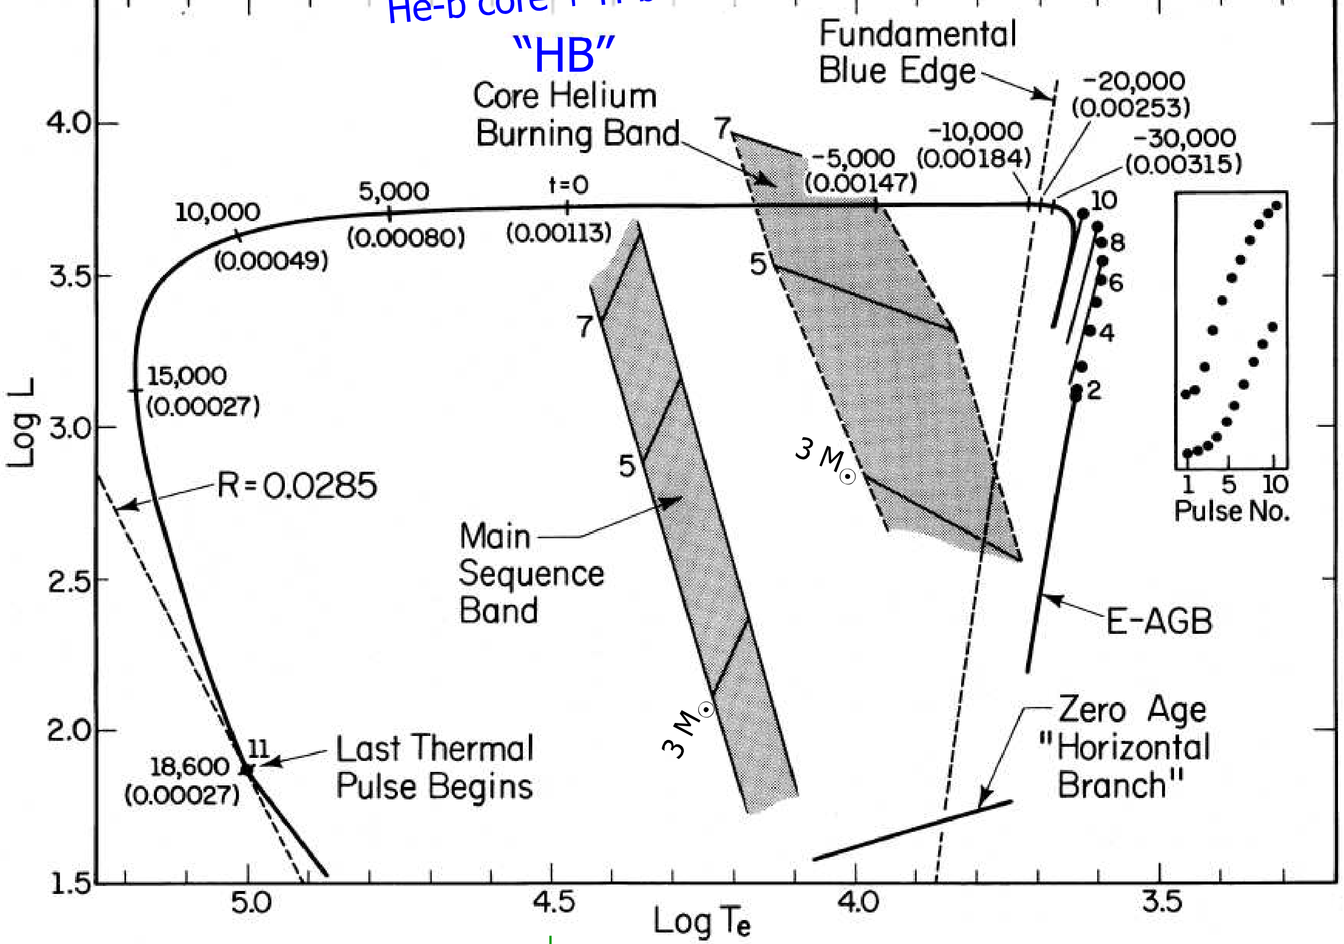
→ Becomes White Dwarf, R=0.0285 $R_\odot$

~ 20,000 km

Instability strip (RR Lyrae)

He-b core + H-b shell

"HB"



11 He-shell flashes

30,000 K

An Introduction to Modern Astrophysics (2nd edition), Bradley W. Carroll & Dale A. Ostlie (1996), p. 509

WDs - general

RG

Extremely low-mass ($M_i \leq 0.2\ M_\odot$) → no He-b → He WD

$M_i \leq 8\ M_\odot$, $T_c < 10^9$ K, No C-burning → CO-core + PN

→ CO WD

$8 < M_i < 10.5\ M_\odot$ → C-b, but no Ne-b

→ ONeMg WD

No fusion reactions, supported by electron degenerate pressure

(Current) Mass : $0.55 – 0.6\ M_\odot$

- min mass $\sim 0.4\ M_\odot$
- max mass for a non-rotating WD = Chandrasekhar mass $\sim 1.4\ M_\odot$

Typical density $\sim 10^6$ g/cm^3

Typical B $\sim 10^6$ Gauss (2×10^3 - 10^9 Gauss)

Binary – mass transfer from a companion → CO WD mass approaches the Chandrasekhar mass → C-detonation → SN Ia

Evolution : hot WD → E decreases, color reddens → black dwarf (timescale > 13.8 Gyr)

→ no black dwarf yet formed

2. Neutron Stars (NSs, 중성자별)

- $M_i \geq 8\ M_\odot$
- $M_f > 1.4\ M_\odot$ → degenerate electron gas pressure cannot hold off gravity → matter is crushed to very high densities → inverse- β decay occurs :

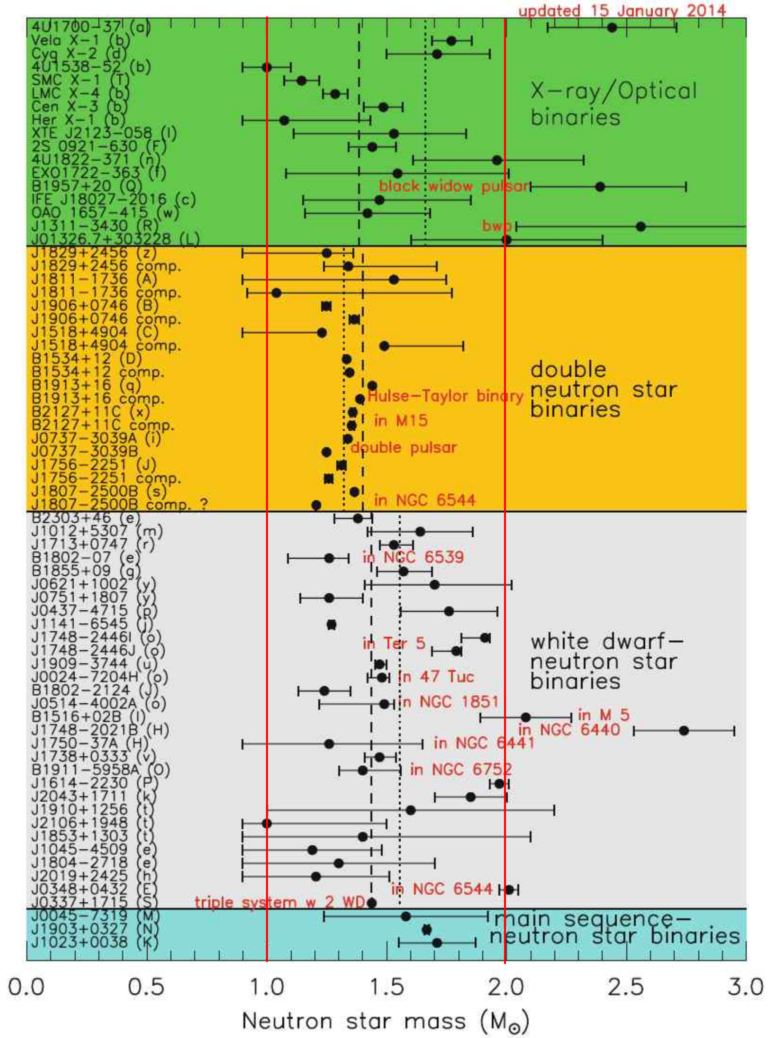
$$p^+ + e^- \rightarrow n + \nu$$

(protons and electrons are squeezed into neutrons)

- Degenerate neutron gas → provides internal pressure
- Mass : 1.1 – 2 $M_\odot$ (upper limit ~ 3 $M_\odot$)

Typical mass ~ 1.4 $M_\odot$
Typical radius ~ 10 km
Typical density ~ 4 × 10^{14} g/cm^3
(400,000 ton/mm^3)
B ~ 10^{12} Gauss
Surface temp ~6 × 10^5 K

※ 1 Tesla = 10^4 Gauss
※ Sun : mean density ~ 1.408 g/cm^3
$B_\odot$~1-2 Gauss
※ Earth : $B_\oplus$~0.1 Gauss
※ Magnetic Resonance Imager (MRI, 자기공명영상) :
B~10^5 $B_\oplus$ ~ 1 Tesla



Horvath & Valentim 2017, Handbook of Supernovae, Volume 2, p. 1317

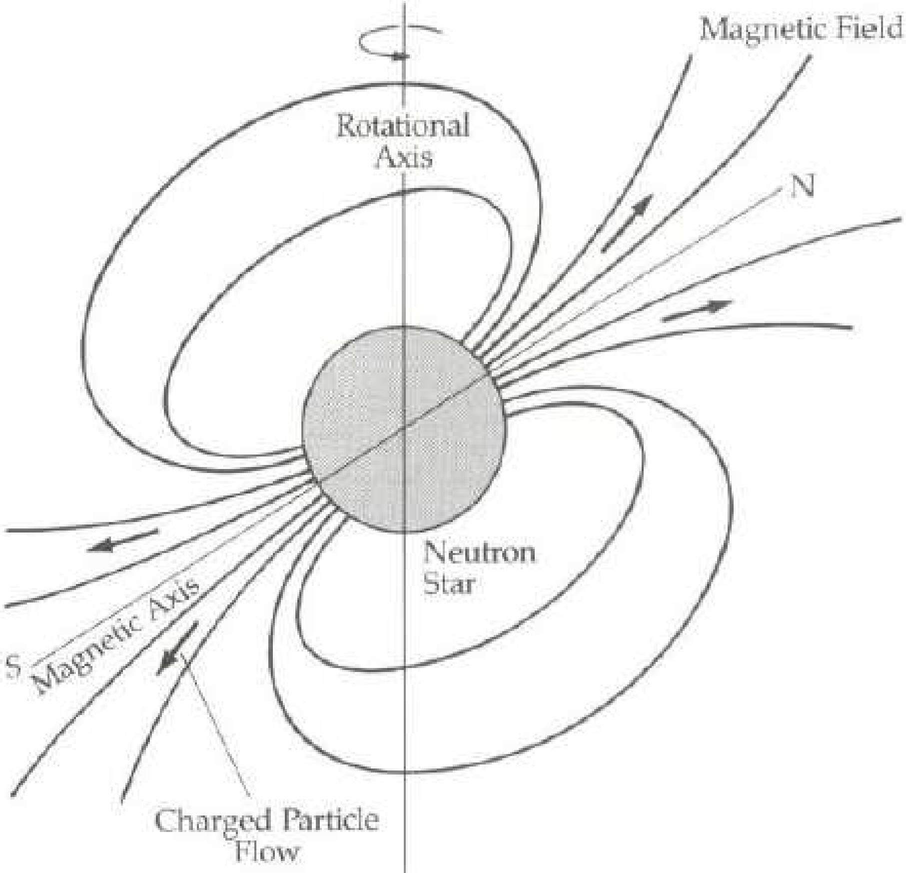
2-1. Pulsars (펄사)

- pulsating star = pulsar = rotating neutron stars
- 1967 discovered by Jocelyn Bell Burnell and Anthony Hewish (1974 Nobel prize)
  Radio pulses coming every 1.33730113s (at 81.5 MHz)+ 3 more objects
- Now, N~2300, P~1.6×10^{-3} to 4.0 s (average 0.65 s)

- Strong magnetic field
  → Synchrotron radiation along the magnetic dipolar axis

- Lighthouse model : transforms the rotational energy into electromagnetic energy → emits through the magnetic axes → pulse period = rotation period

- If the Sun becomes a NS → R = 7 km



magnetic axis is inclined with respect to the rotation axis

TABLE 17–1 Properties of Selected Pulsars

Name (PSR)	Period (s)	dP/dt (10^{-15} s/s)	DM(pc/cm^3)
1937 + 21	0.001557	1.07×10^{-4}	71.2
1855 + 09	0.005362	46421	13.3
0531 + 21 (Crab)	0.033326	421	56.8
0833 − 45 (Vela)	0.089234	124	69.1

Introductory Astronomy and Astrophysics (4th edition)
Michael Zeilik & Stephen A. Gregory (1998), p. 339, 341

2-1. Pulsars (펄사)

- Dispersion : a given pulse arrives at the Earth later as we look at lower frequencies
  - Due to a slowing down of the photon velocity by electrons in the line-of-sight (los)
  - Longer λ are slowed down more
  - Observations can tell us the mean electron density in the los
- If pulses of ν_1 and ν_2 $(\nu_1 > \nu_2)$ are emitted at time t_0 → they arrive at t_1 and t_2, respectively
- Then, $t_1 - t_0 = \dfrac{d}{v_1}$ and $t_2 - t_0 = \dfrac{d}{v_2}$
- We can measure $t_2 - t_1$ → equal to $(\dfrac{1}{v_2} - \dfrac{1}{v_1})d$
- Velocities depend on the electron density → if we know the electron density, we can get the distance
- Dispersion Measure (DM) = integrated electron density : $\mathrm{DM} = \int_0^d n_e \, dl$

TABLE 17–1 Properties of Selected Pulsars

Name (PSR)	Period (s)	dP/dt (10^{-15} s/s)	DM(pc/cm^3)
1937 + 21	0.001557	1.07×10^{-4}	71.2
1855 + 09	0.005362	46421	13.3
0531 + 21 (Crab)	0.033326	421	56.8
0833 − 45 (Vela)	0.089234	124	69.1

Introductory Astronomy and Astrophysics (4th edition)
Michael Zeilik & Stephen A. Gregory (1998), p. 339-340

Binary pulsars (쌍성 펄사)

- First binary pulsar, PSR B1913+16 : 1974 at Arecibo by Joseph H. Taylor, Jr. (조세프 테일러, b. 1941), Russell Hulse (러셀 헐스, b. 1950)
- "Hulse-Taylor binary pulsar"

- Einstein's theory of general relativity → two NSs would emit gravitational waves as they orbit a common center of mass
- Gravitational waves carry away orbital energy → cause the two stars get closer → orbital P ↓

The Nobel Prize in Physics 1993

Russell A. Hulse and Joseph H. Taylor Jr. "for the discovery of a new type of pulsar, a discovery that has opened up new possibilities for the study of gravitation"

https://www.nobelprize.org/prizes/lists/all-nobel-prizes-in-physics/

https://en.wikipedia.org/wiki/Binary_pulsar

3. Black Holes (BHs, 검은구멍)

- A region of spacetime in which gravity is so strong that nothing (incl. light) can escape it
- Minimum mass ~ 3 $M_\odot$
- Theoretically zero volume and infinite density → "singularity" (breakdown of the laws of physics)
- An object with escape speed v_{esc} at the surface of the BH :

$$\text{Total Energy} = \text{KE} + \text{PE} = \frac{mv_{esc}^2}{2} - \frac{GmM}{R} = 0$$

- Assuming max escape velocity = c

$$\boxed{R = \frac{2GM}{c^2} = 3M \text{ km}}$$

Schwarzshild radius

black_hole_baird.jpg
http://sciencequestionswithsurprisinganswers.org/2013/06/18/can-you-go-fast-enough-to-get-enough-mass-to-become-a-black-hole/

- If the Sun becomes a BH → density ~10^{16} g/cm^3 (~nucleus of an atom)
- If an object cross the Schwarzshild radius, it crashes into a singularity (zero volume)

3. Black Holes (BHs, 검은구멍)

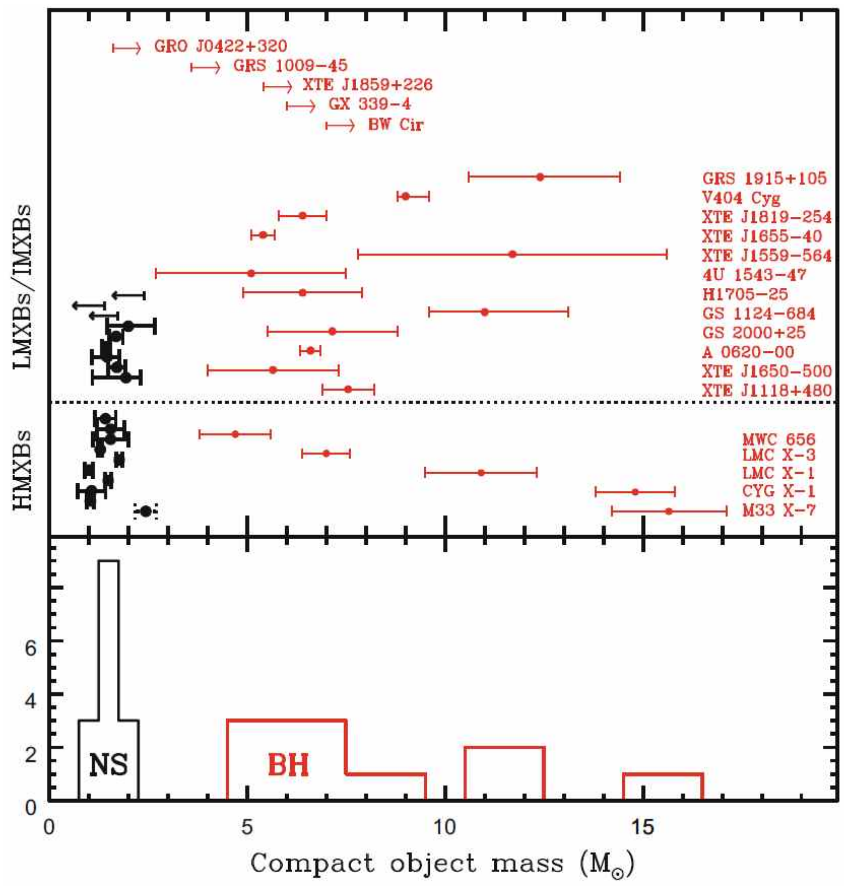


Fig. 2 *Top*: compact remnant masses measured in X-ray binaries. Neutron stars and black holes are indicated in *black* and *red colors*, respectively. 4U 1700-37 is plotted in *dotted-style line* because the nature of the compact star is uncertain. The *horizontal dotted line* divides LXMBs/IMXBs from HMXBs. *Bottom*: observed distribution of neutron stars and black hole masses

J. Casares et al. 2017, Handbook of Supernovae, Volume 2, p. 1499

3. Black Holes (BHs, 검은구멍)

- How to observe/find a BH?
- not for an isolated BH → but for a BH in a binary system (interactions with other material)
- matter falling toward a BH - gains kinetic energy → heats up, becomes ionized → emits electromagnetic radiation
- If T reaches a few $\times 10^6$ K → emits X-rays
- accreted material + initial angular momentum → form a disk around the BH : accretion disk (강착원반) = X-ray source
