# Hertzsprung-Russell Diagram

1911 Ejnar Hertzsprung

Danish engineer and amateur astronomer

1913 Henry Norris Russell

US, Princeton University

1913 – published the “diagram”

80-90% of all stars – main sequence (MS) stars

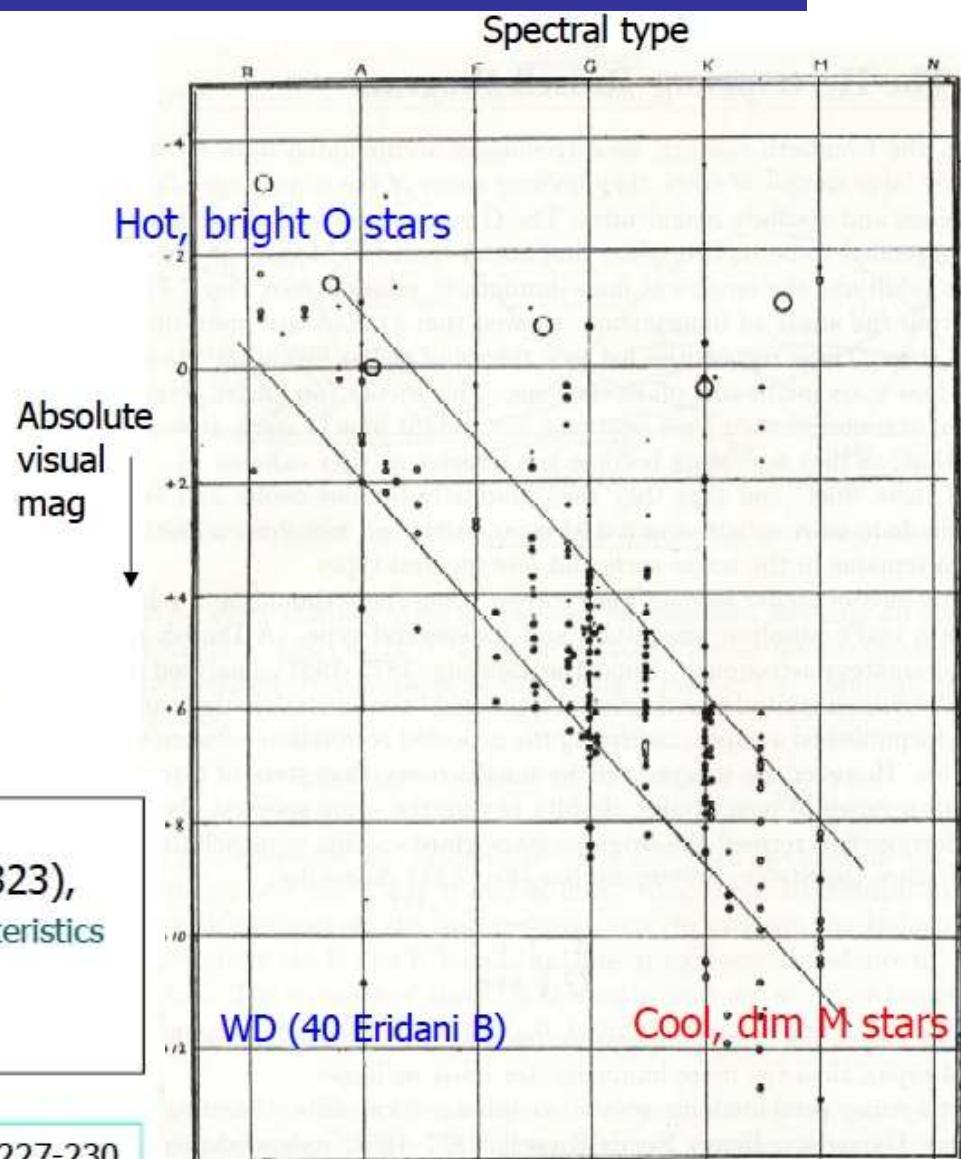

\* Bengt Strömgren (1908-1987, Danish)

: suggested the name “H-R” diagram

Fig 8.10 Henry Norris Russell's first diagram  
(Russell, H. N. 1914 May 07, Nature, 93 (Number 2323),  
252-258 'Relations Between the Spectra and other Characteristics  
of the Stars. II. Brightness and Spectral Class')

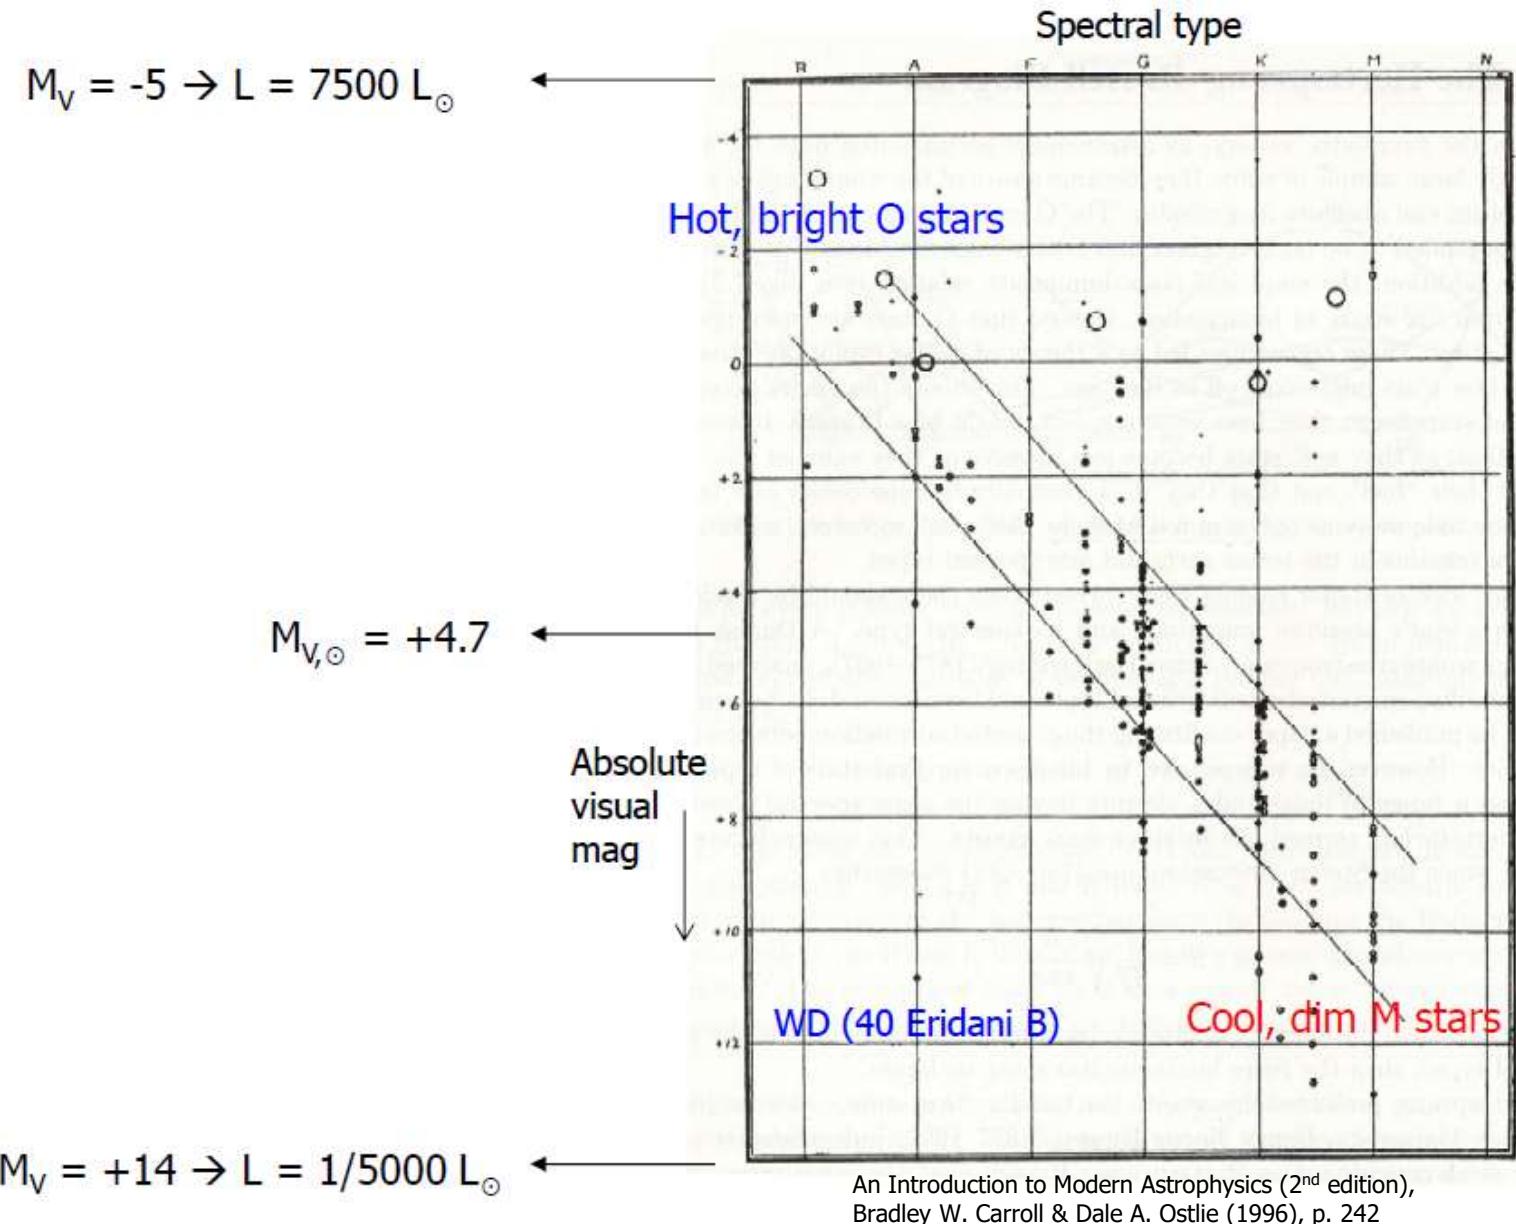

Fig. 1. > 200 stars

\* (Russell, H. N. 1914 April 30, Nature, 93 (Number 2322), 227-230  
'Relations Between the Spectra and other Characteristics of the  
Stars. I. Historical')

An Introduction to Modern Astrophysics (2<sup>nd</sup> edition),  
Bradley W. Carroll & Dale A. Ostlie (1996), p. 242

# Hertzsprung-Russell Diagram

# Main Sequence (MS, 주계열성)

'Sequence'

NAVER 영영사전

sequence 미국식 [ˈsi:kwəns] 영국식 [ˈsi:kwəns]

1. 명사 the order in which things happen or should happen
2. 명사 a group of things that come one after the other, series
3. 명사 a part of a movie, television show, etc., that deals with one subject, action, or idea

sequence 유의어

n. chain, cycle, series, arrangement, order, progression, succession

계열 系列 [발음 : 계 : 열/계 : 열]

파생어 : 계열적

명사

1. 서로 관련이 있거나 유사한 점이 있어서 한 갈래로 이어지는 계통이나 조직.

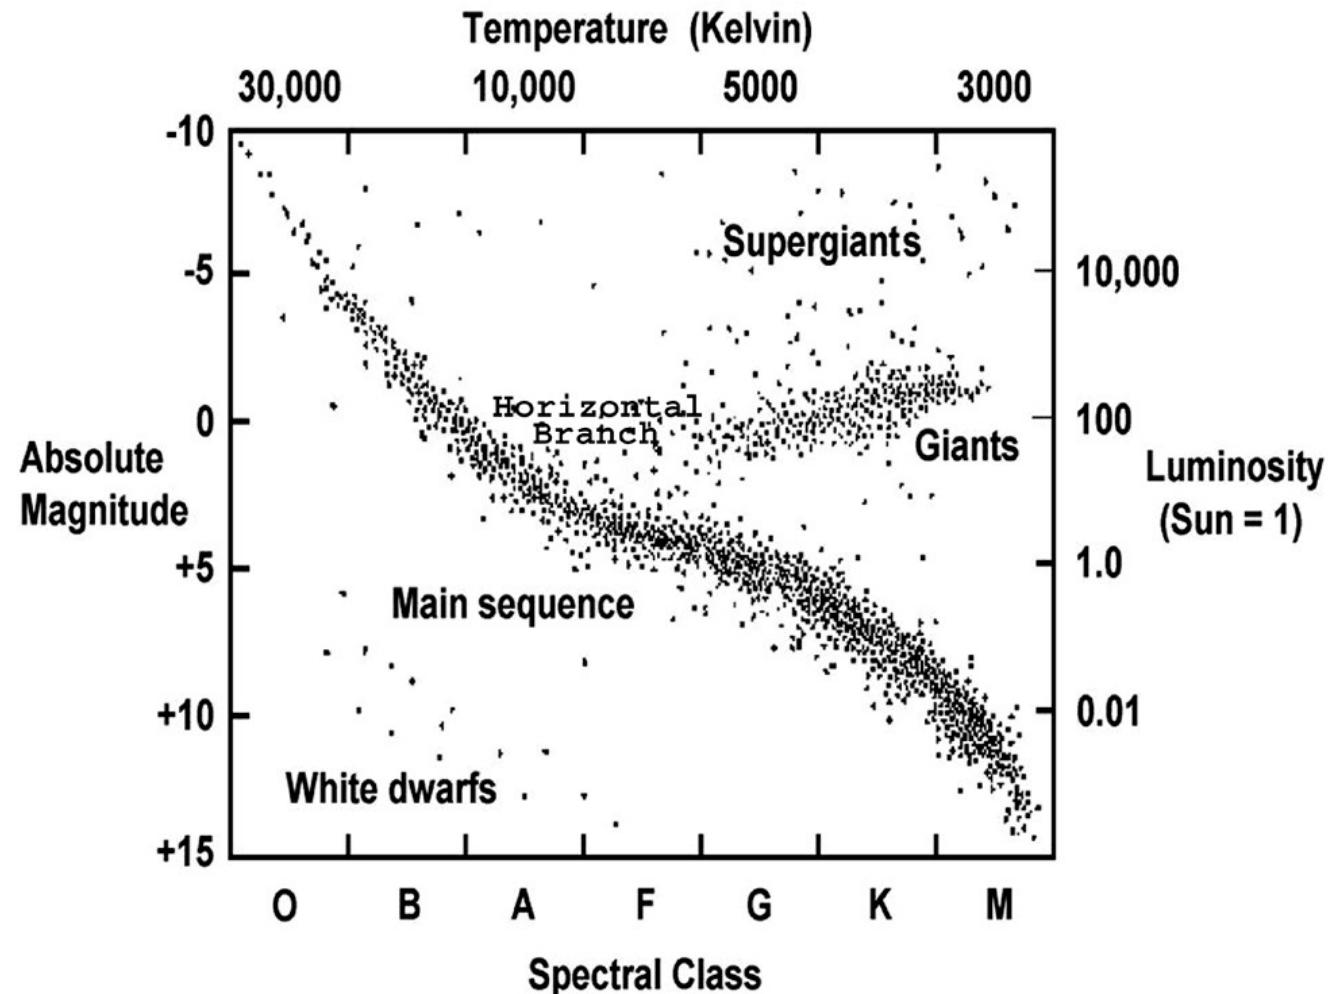

- 인문 계열
- 영상섭의 소설은 사실주의 계열의 작품이다.
- 교내 계열 평균에서 13반인 꼴등입니다. 출처 : 전상국, 퇴장

2. <경제> 기업의 결합 형태의 하나. 생산, 판매, 자본, 기술, 중역 파견 따위에 따라 대기업 상호 간 또는 대기업과 중소기업 간에 볼 수 있는 기업 결합이다.

- 계열 산업.

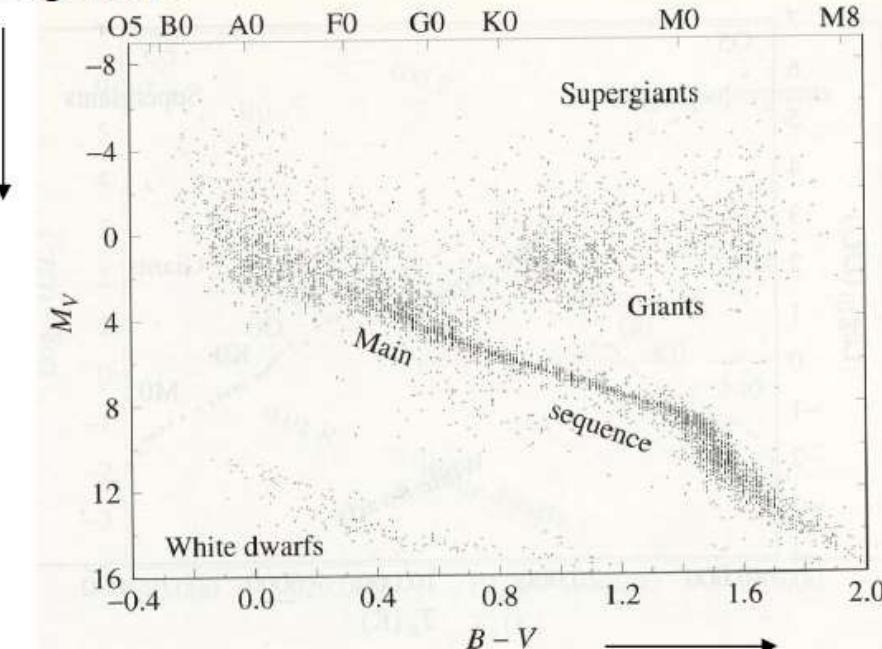

# Main Sequence (MS, 주계열성)

Vega : A0 V

Color-Magnitude Diagram (CMD)

(색등급도)

luminosity

Effective temperature

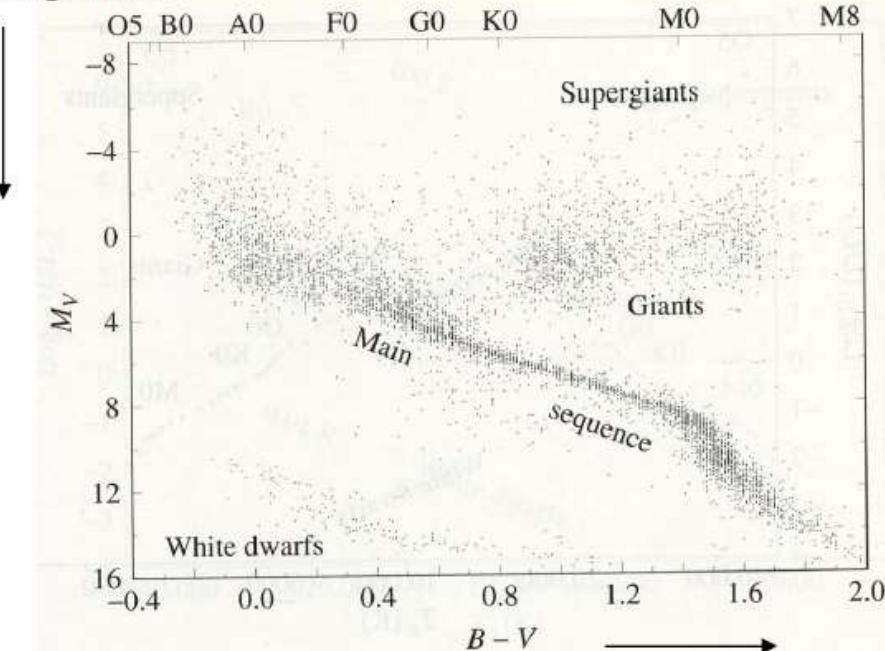

Fig 8.12 A theorist's H-R diagram  
(log-log plot)

HR Diagram (HRD)

(HR도)

# Observer's vs Theoriest's H-R diagrams

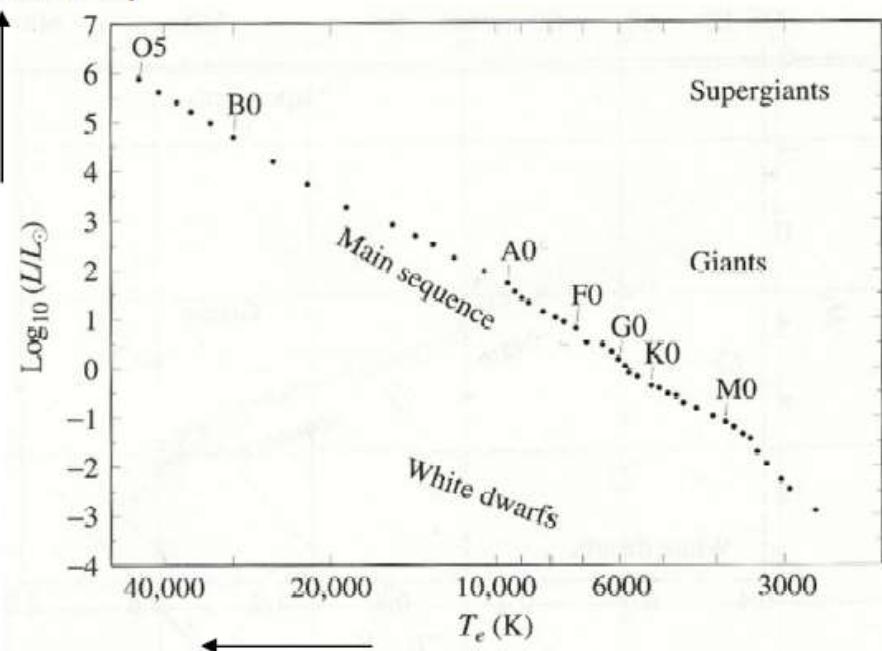

magnitude

Color index  
(Spectral type)

MS width ← (1) changes in T, L in the MS  
(2) Slight differences in the components of stars

luminosity

Effective temperature

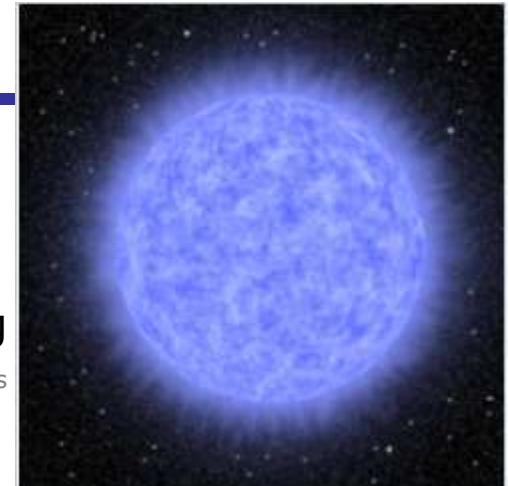

MS luminosities :  $5 \times 10^{-4} L_\odot$  to  $1 \times 10^6 L_\odot$   
→ over 10 orders of mag

# Spectral types

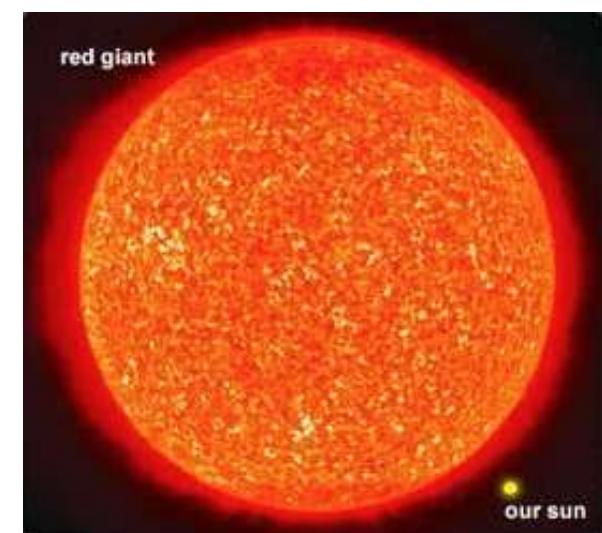

- O type : blue stars. Usually supergiants.  
Very luminous and hot. Rare.  
Strong helium absorption lines.

$\zeta$  Puppis (O4 I) – artist's rendering

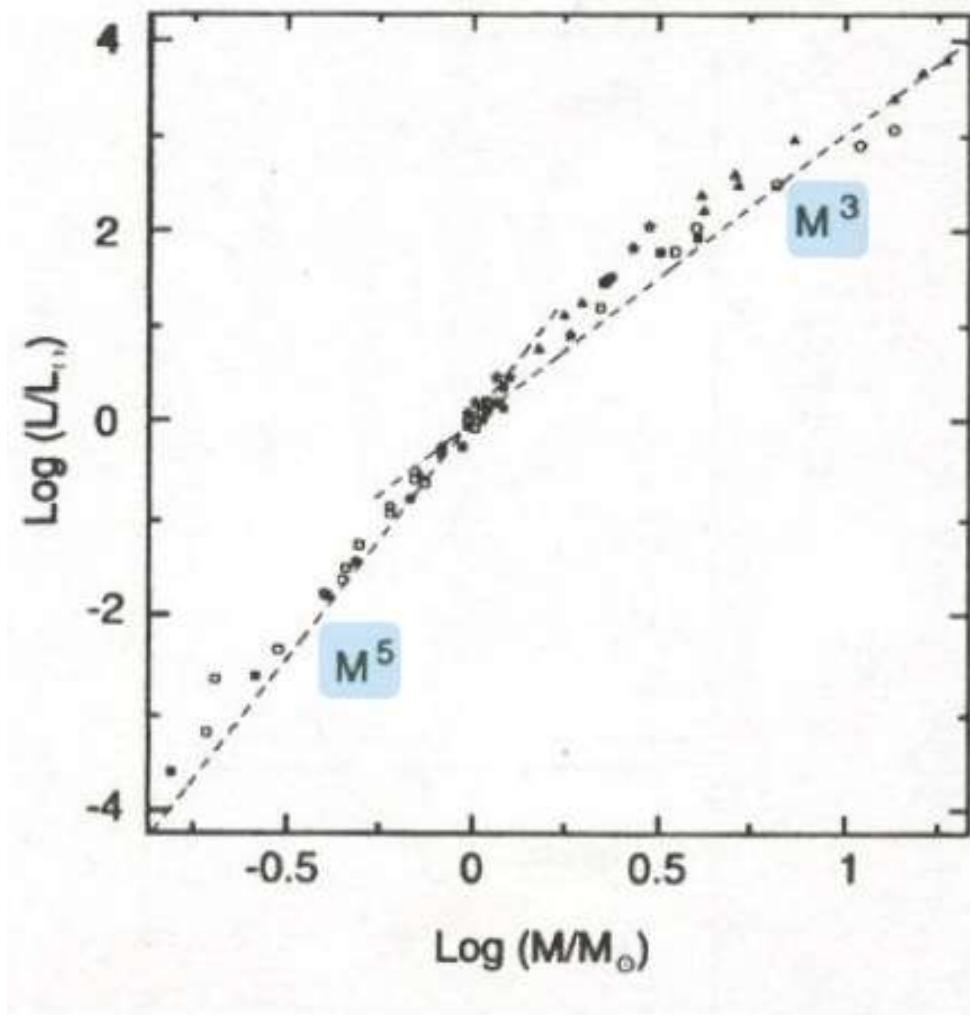

[https://en.wikipedia.org/wiki/Zeta\\_Puppis](https://en.wikipedia.org/wiki/Zeta_Puppis)

- B type : blue white stars. Mainly giants. Neutral He and H absorption lines.
- A type : white stars. Strong **H absorption lines**.
- F type : yellow white stars. Weak H and ionized Ca absorption lines.
- G type : yellow stars. Strong Ca absorption lines.
- K type : orange stars. Metallic absorption lines.
- M type : red stars. Strong metallic absorption lines.

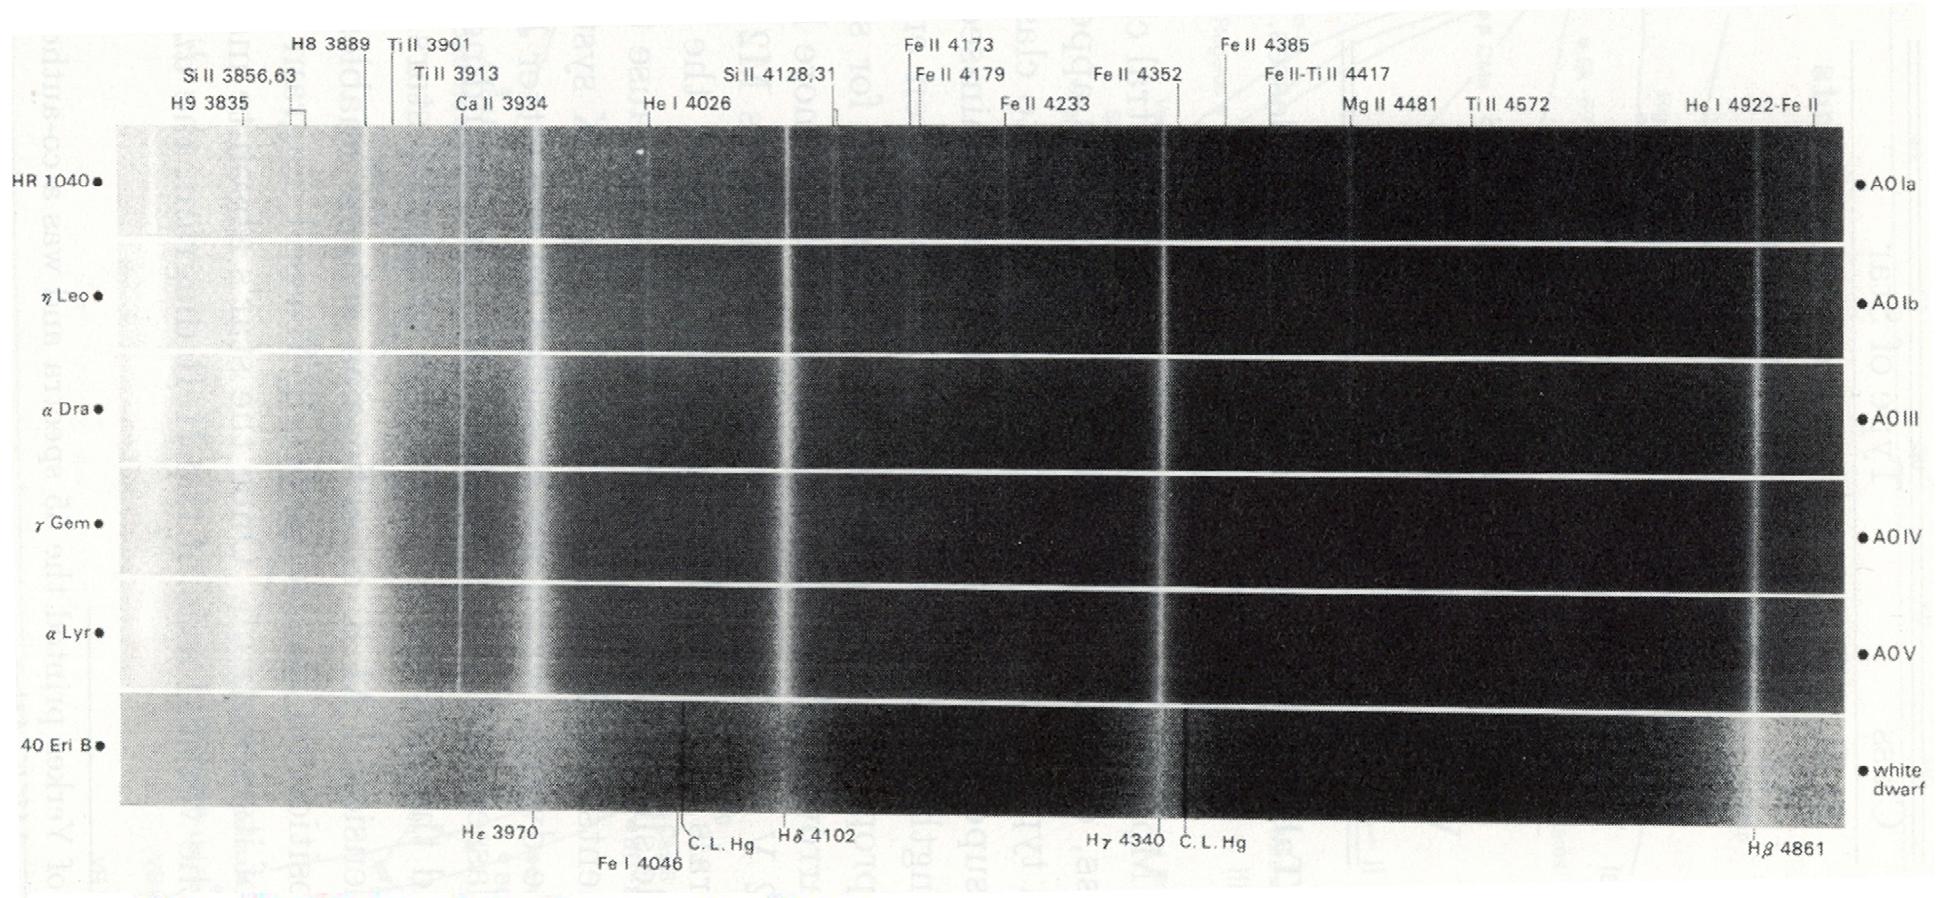

## Stars → mass-luminosity relation

O stars : more luminous than M stars  
→ O stars are more massive than M stars

$$\text{Power-law : } L \propto M^{\nu}$$
$$\nu = 3 - 5$$

# 'A' type stellar spectra – hydrogen Balmer lines

More luminous stars → narrower lines

$$\text{Stefan-Boltzmann equation } L = 4\pi R^2 \sigma T^4$$

$\sigma$  : Stefan-Boltzmann constant

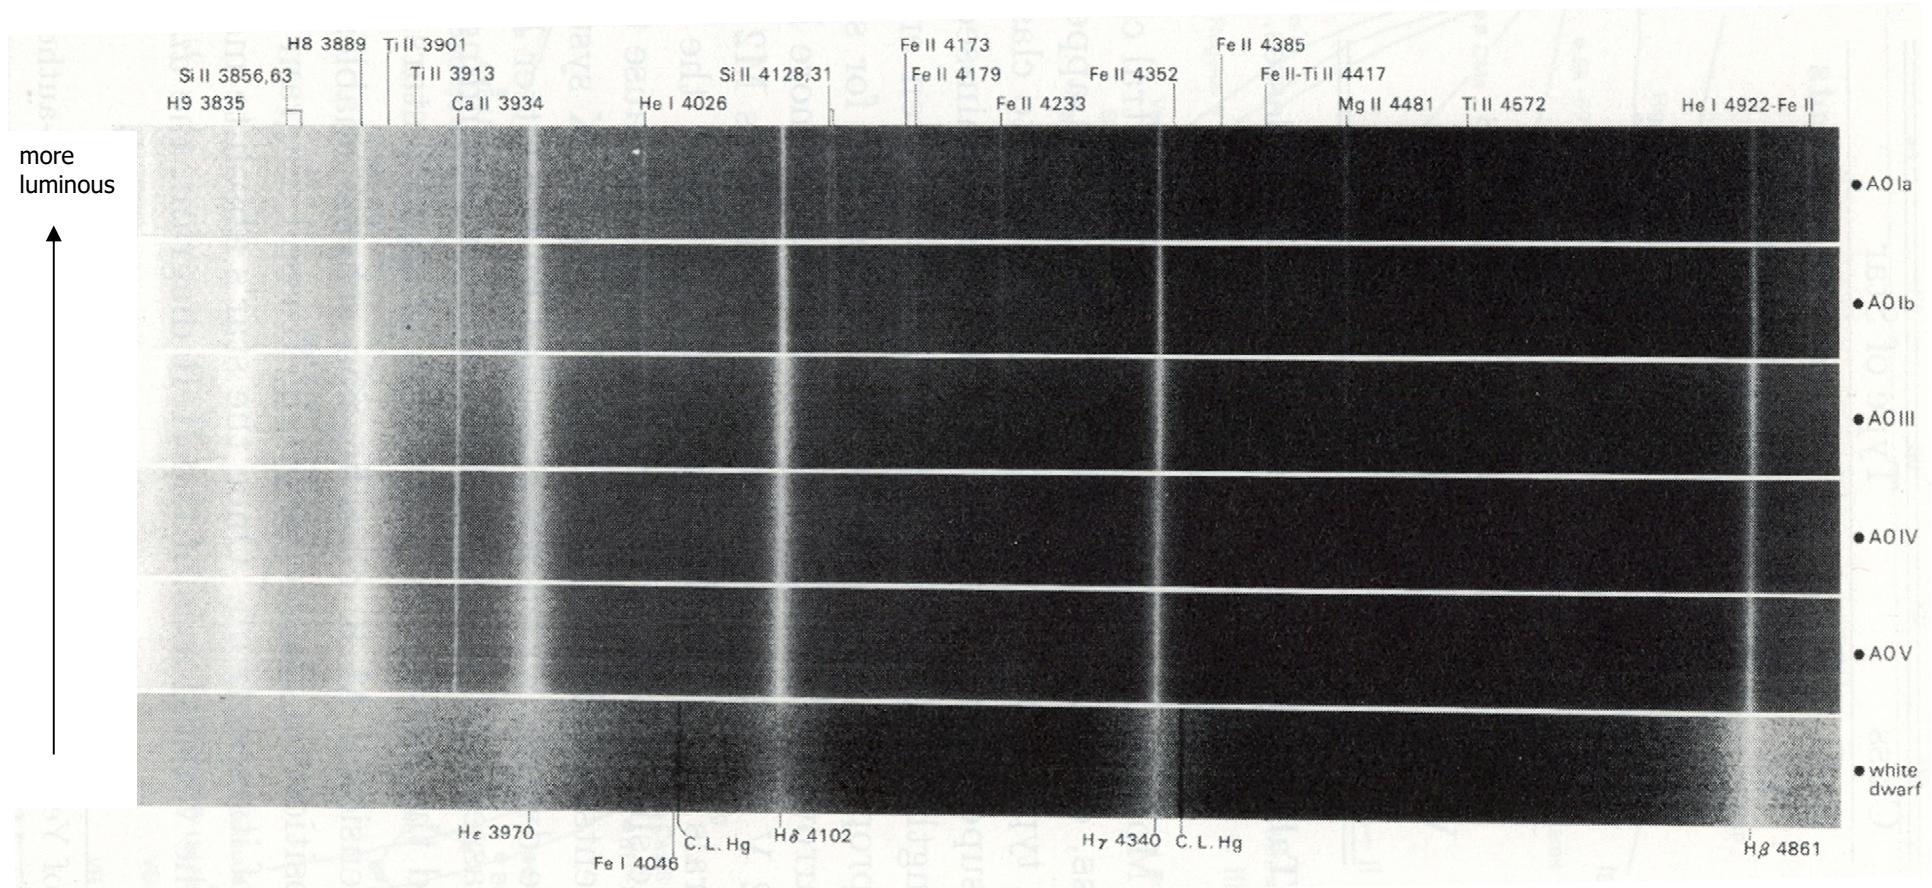

$$\sigma = 5.67 \times 10^{-5} \text{ erg cm}^{-2} \text{ sec}^{-1} K^{-4}$$

$$\sigma = 5.67 \times 10^{-8} W m^{-2} K^{-4}$$

T : same

$L \propto R^2$  → less dense → fewer collisions between atoms → less broadening

# 'A' type stellar spectra – hydrogen Balmer lines

More luminous stars → narrower lines

$$\text{Stefan-Boltzmann equation } L = 4\pi R^2 \sigma T^4$$

T : same

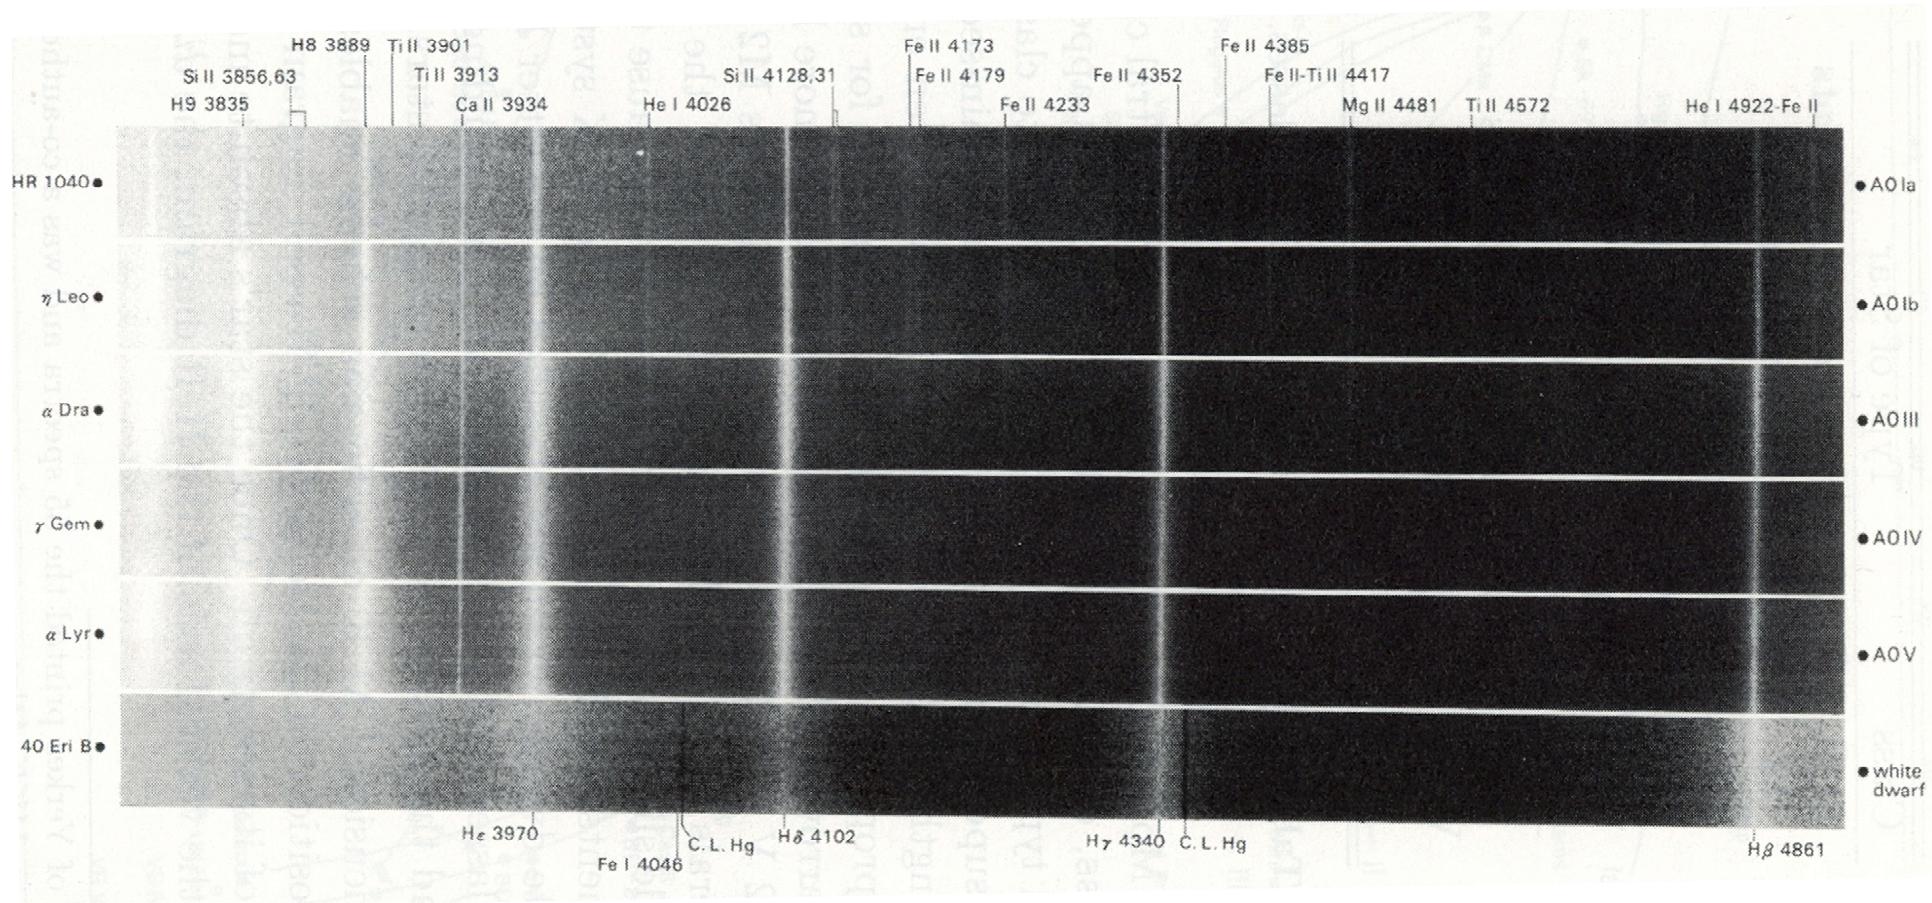

$L \propto R^2 \rightarrow$  less dense → fewer collisions between atoms → less broadening

$\sigma$  : Stefan-Boltzmann constant

$$\sigma = 5.67 \times 10^{-5} \text{ erg cm}^{-2} \text{ sec}^{-1} K^{-4}$$

$$\sigma = 5.67 \times 10^{-8} W m^{-2} K^{-4}$$

# 'A' type stellar spectra – hydrogen Balmer lines

1943 Yerkes Observatory

William W. Morgan – Phillip C. Keenan - Edith Kellman

『An Atlas of Stellar Spectra』 (Chicago: Chicago University Press)

→ M-K (MKK) spectral classification system : two-dimensional spectral classification

# Morgan-Keenan Luminosity Classes

Class	Type of Star
Ia-O	Extreme, luminous supergiants (SGs)
Ia	Luminous SGs
Ib	Less luminous SGs
II	Bright giants
III	Normal giants
IV	Subgiants
V	Main-sequence (dwarf) stars
VI, sd	Subdwarfs
D	White dwarfs

- Same spectral type
- Same effective temperature
- Only luminosity differences ← subtle differences in the relative strengths of spectral lines

# H-R diagram – luminosity classes

Betelgeuse (=α Orionis) ←  
: M2 Ia (or M2 Iab) – pulsating variable

Sun : G2 V

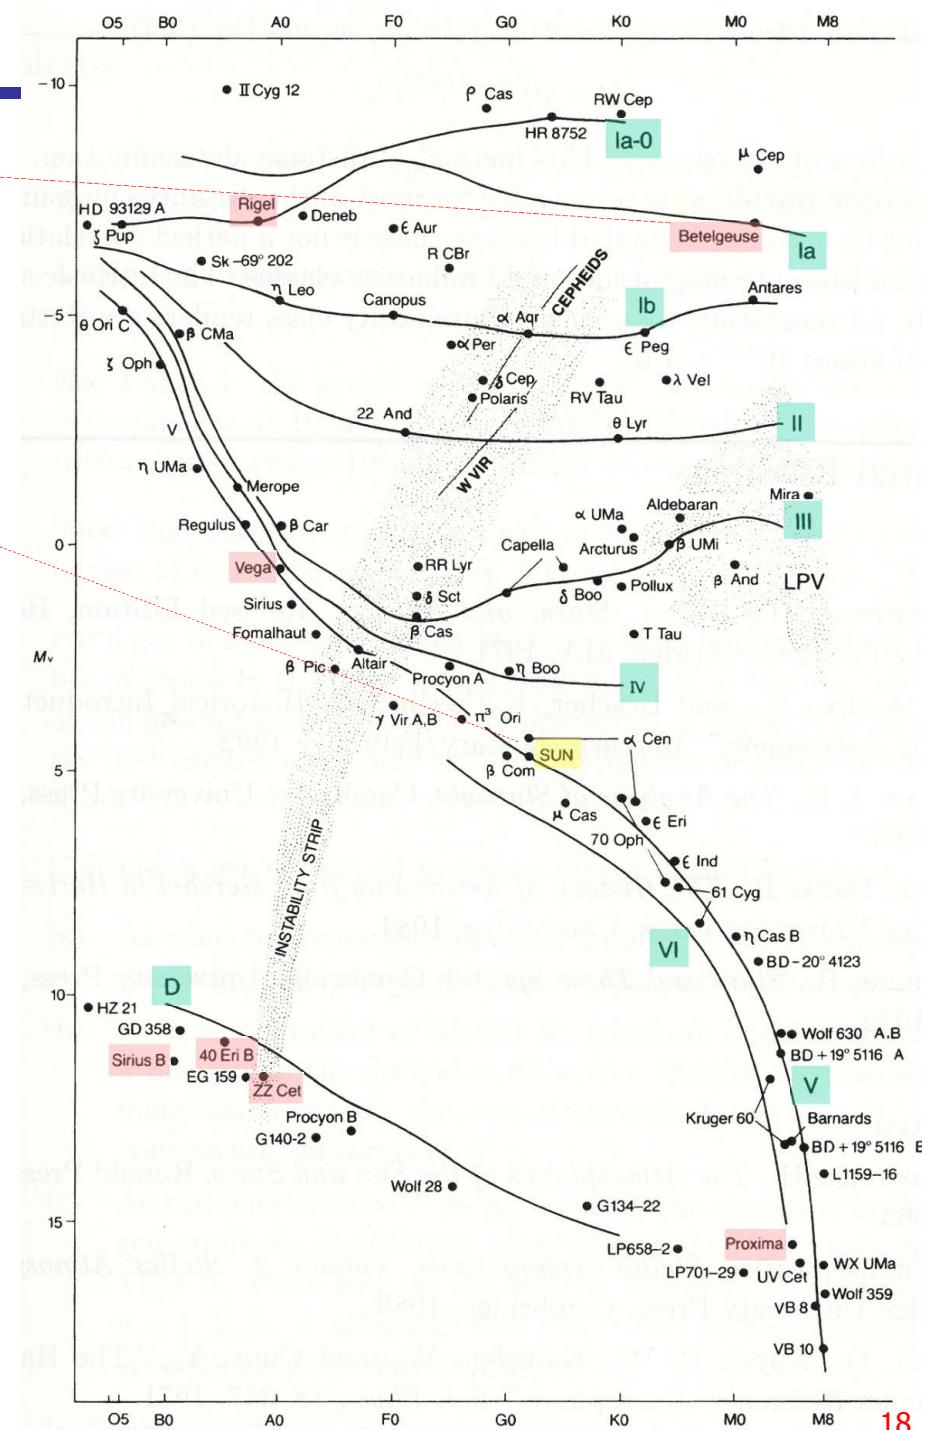

- A star's position is fixed in H-R diagram

→ Vertical reading = absolute magnitude ( $M_V$ )

→ Distance can be calculated by

$$(m-M)_0 = V - M_V - A_V = 5 \log d - 5$$

**“spectroscopic parallax”**

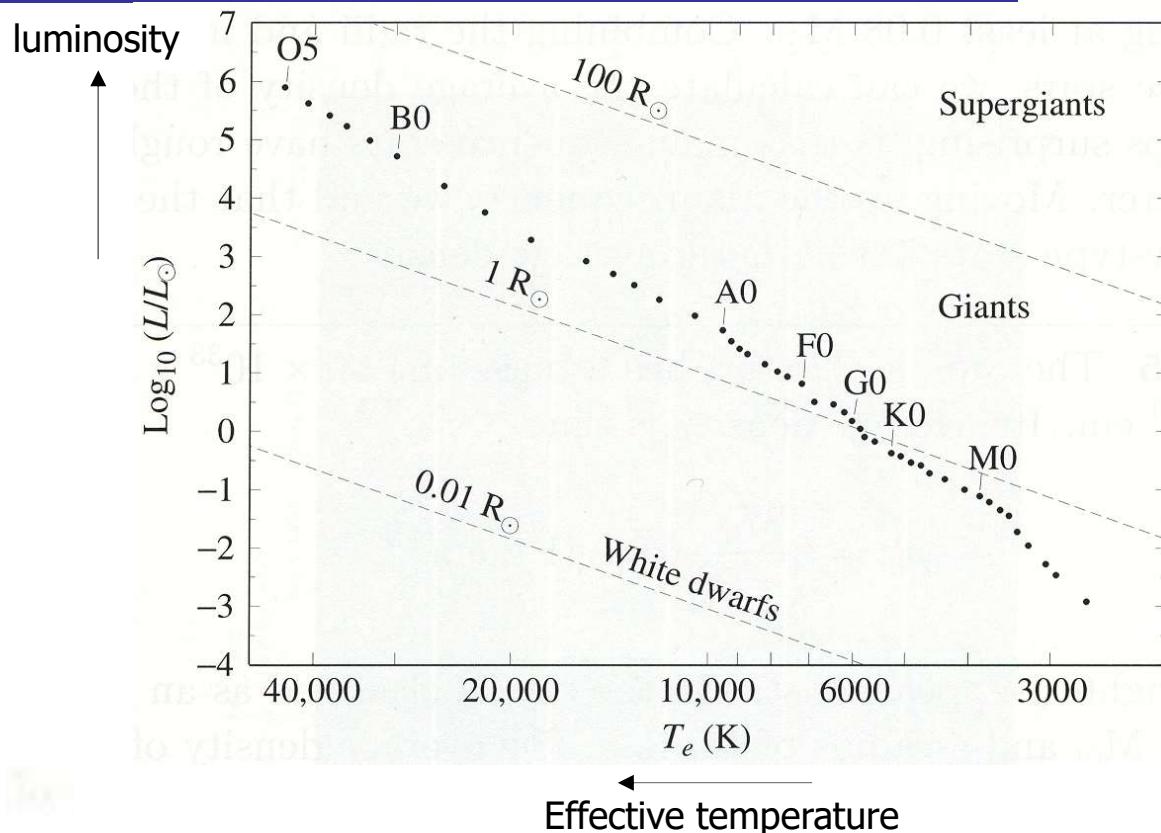

# Line of constant radius

$$L = 4\pi R^2 \sigma T^4$$

$100 \times L$   
 $\rightarrow 10 \times R$  larger

**Giant stars :  $10 - 800 R_{\odot}$**   
(e.g. Aldebaran,  $\alpha$  Tauri :  $45 R_{\odot}$ )

**Supergiant stars**  
(e.g. Betelgeuse,  $\alpha$  Orionis – pulsating variable star :  
 $700 - 1000 R_{\odot}$ ,  $P = 2070$  d)

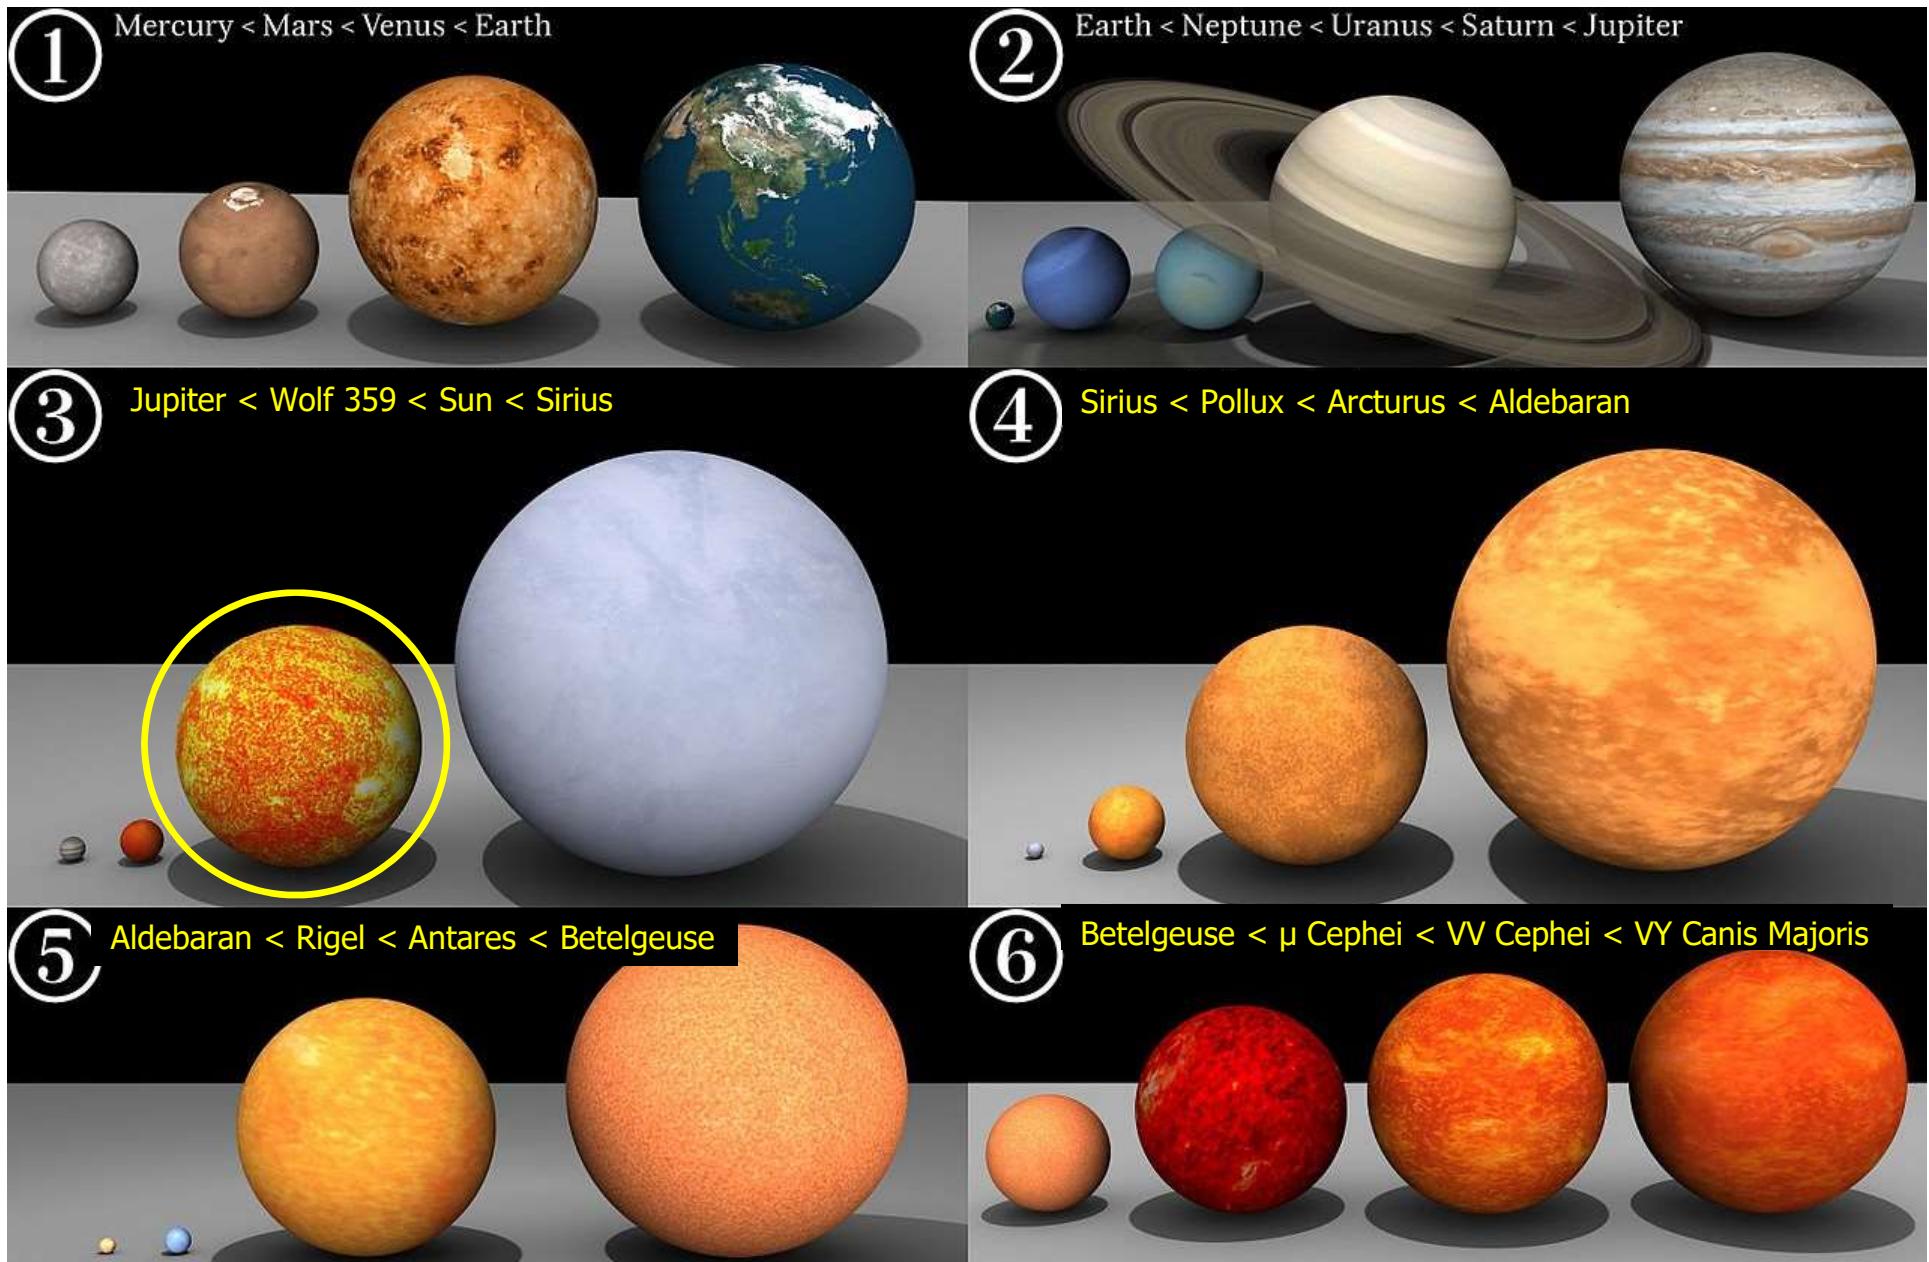

- \*  $\mu$  Cephei :  $1260 R_{\odot} = 5.9$  AU
- \* VY Canis Majoris :  $1420$  or  $2069 R_{\odot} = 6.6$  or  $9.7$  AU

- \*  $1000 R_{\odot} = 4.7$  AU
- \* Jupiter, semi-major axis  $a = 5.2$  AU
- \* Saturn, semi-major axis  $a = 9.5$  AU

An Introduction to Modern Astrophysics (2<sup>nd</sup> edition),  
Bradley W. Carroll & Dale A. Ostlie (1996), p. 245

# Sizes of stars

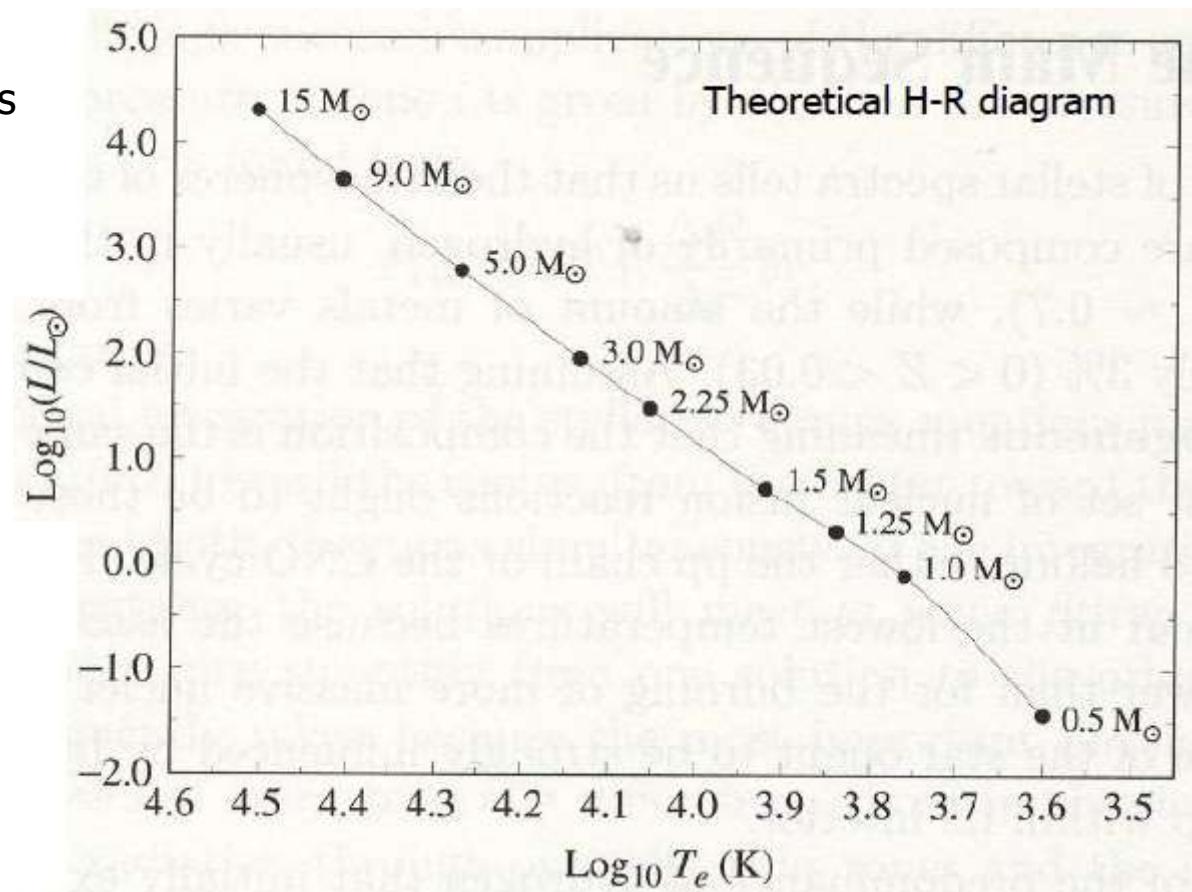

# Vogt-Russell theorem

---

The **mass** and **composition** of a star uniquely determine its **radius**, **luminosity**, and **internal structure**, as well as its subsequent **evolution**.

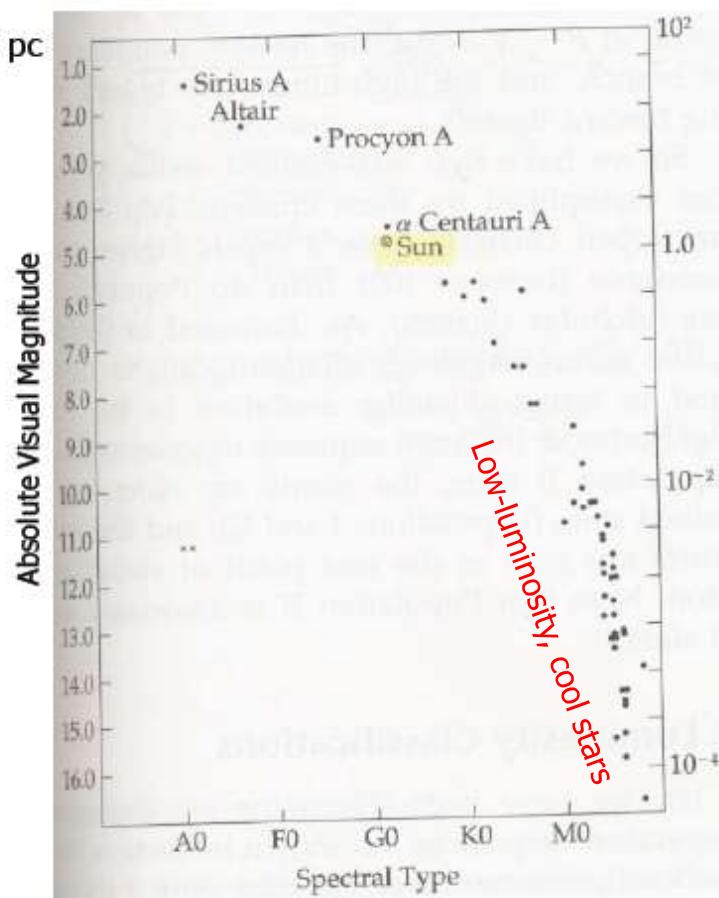

# Stellar masses from models

- Theoretical models for the mass range of core H-b  
→ lie along the observational MS
- $100 - 0.08 M_{\odot}$   
→ Only 3 orders of mag
- At  $< 0.08 M_{\odot}$   
→ brown dwarfs (BDs)

# HR diagrams

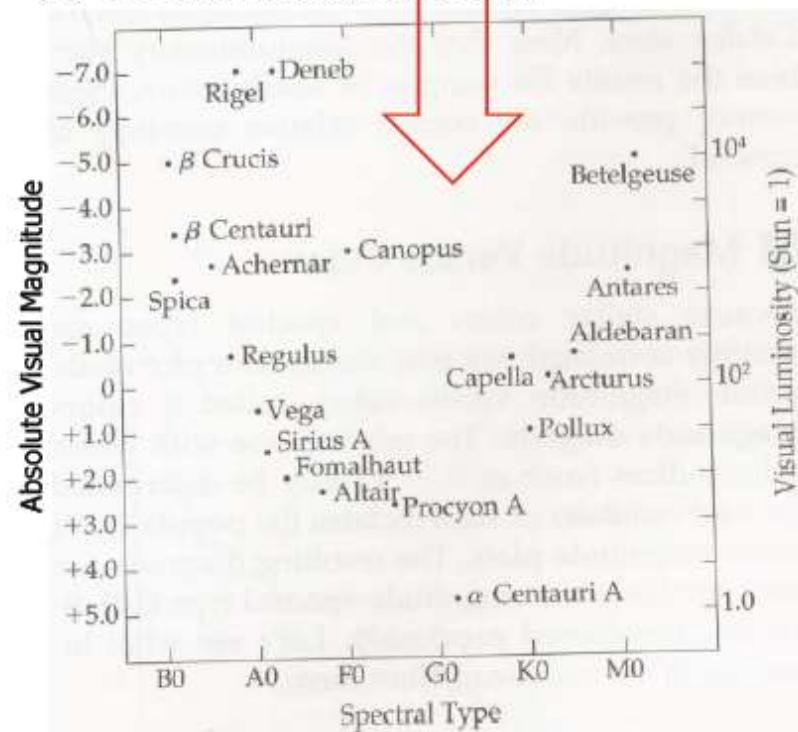

(a) Stars within 5 pc

- Well-defined **MS** + increasing number of stars toward **later spectral types**
- No stars earlier than **A1**

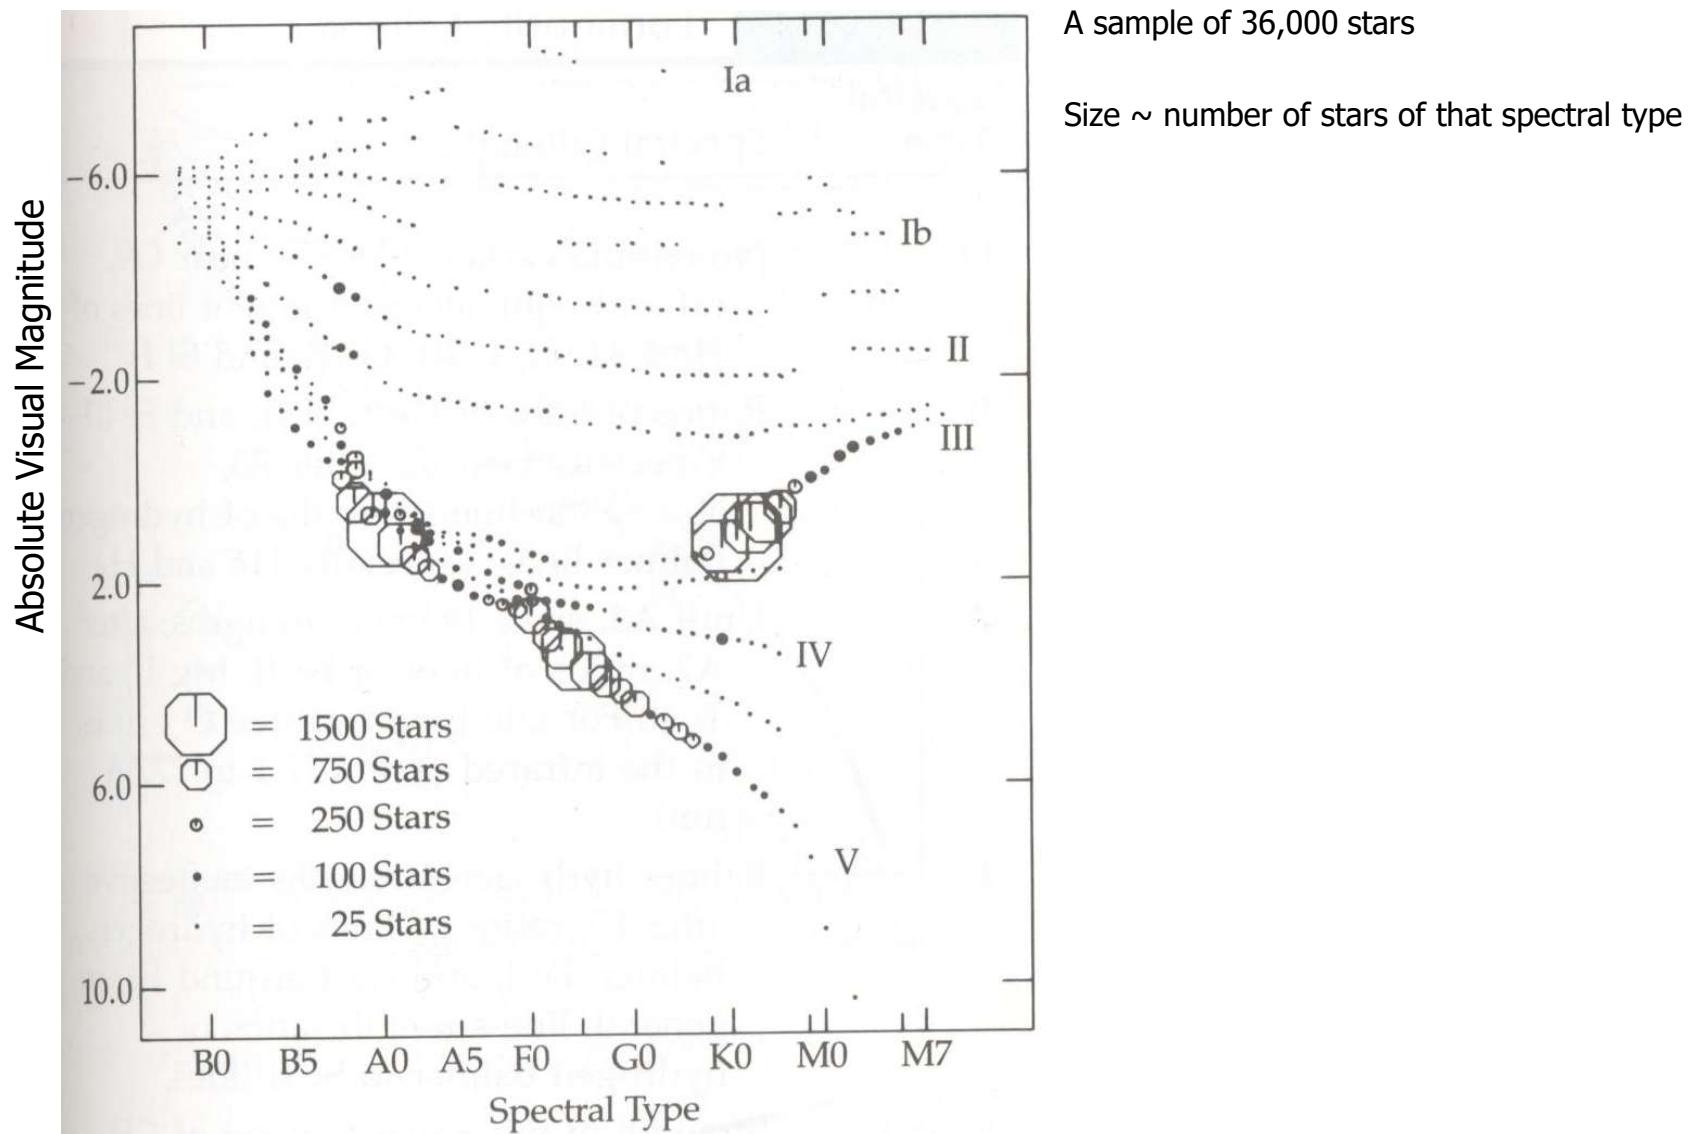

Hertzsprung Gap

(b) The brightest stars in the sky

- A significant number of giants and SGs
- Several early-type **MS** stars

# HR diagrams

# 1. Stars: The Hertzsprung-Russell Diagram (항성: HR도)

## 1.2 Distances (거리)

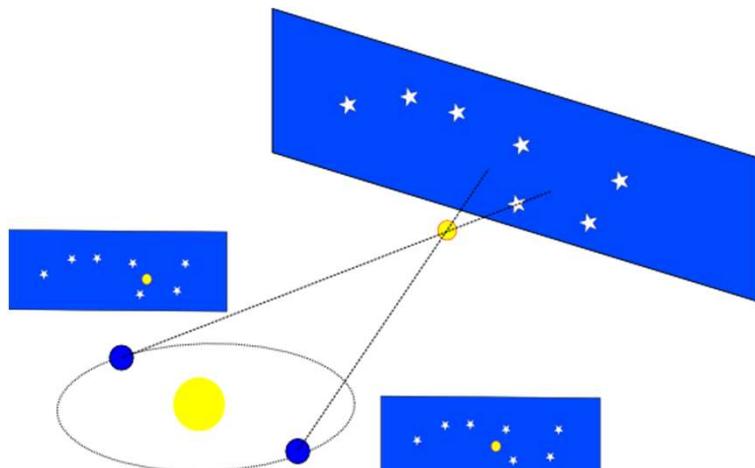

<http://www.centauri-dreams.org/?p=11322>

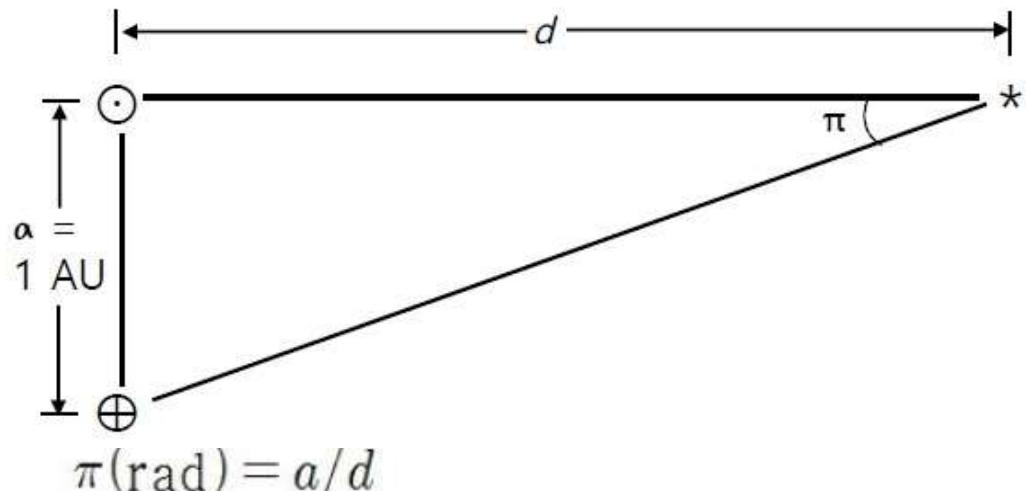

<http://www.centauri-dreams.org/wp-content/uploads/2010/02/light-candles.jpg>

# 1. Trigonometric parallax (삼각시차)

- First detection (1838) : Friedrich W. Bessel → 61 Cygni,  $d=10.4$  ly
- In 1838, Friedrich G. W. von Struve → Vega (= α Lyr),  $d=25.0$  ly

<https://en.wikipedia.org/wiki/Parallax>

- $2\pi \text{ (rad)} = 360^\circ \rightarrow 1 \text{ rad} = 57^\circ 17' 44.81'' = 206265''$

$$\boxed{\pi'' = \frac{1}{d}} \quad (\pi \text{ in arcsec, } d \text{ in parsec [파섹]})$$

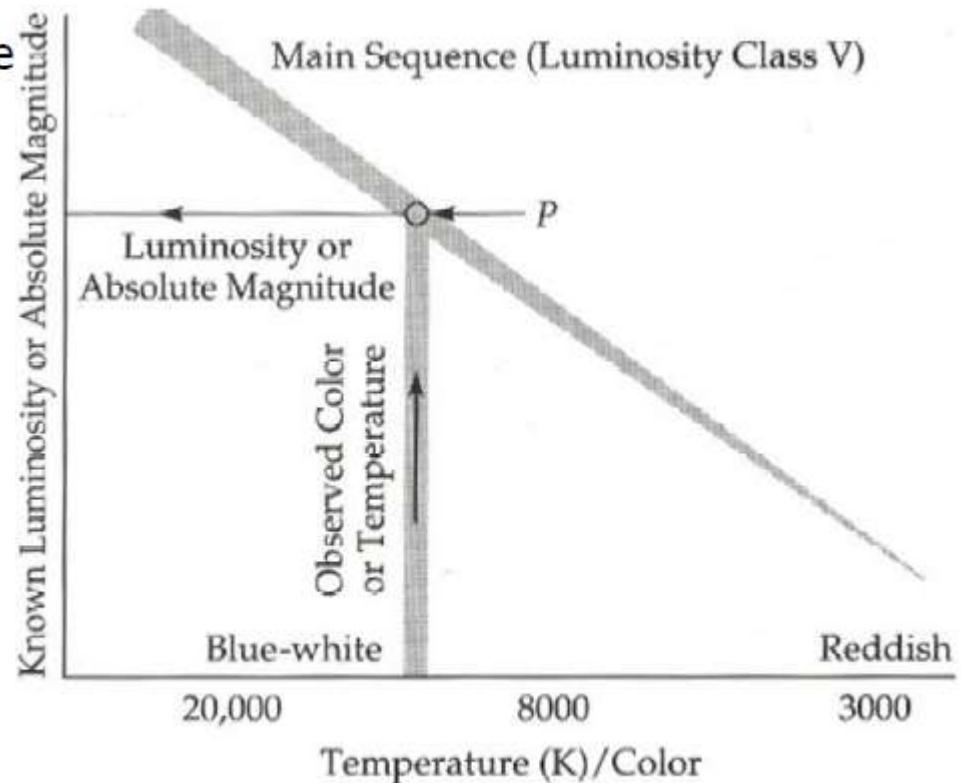

$$1 \text{ pc} = 3.086 \times 10^{18} \text{ cm} = 3.26 \text{ lightyears (광년)}$$

- Largest parallax : Alpha Centauri ( $d=1.3$  pc)  $\rightarrow \pi=0.76''$
- Ground-based observations  $\rightarrow$  error  $\sim \pm 0.004''$   
 $\rightarrow$  accurate only to  $\pi=0.001''$  ( $d \sim 100$  pc)

→ Satellites : Hipparcos (1989-1993), Gaia (2013 Dec 19-)

# Spectroscopic parallax – using **spectral type**

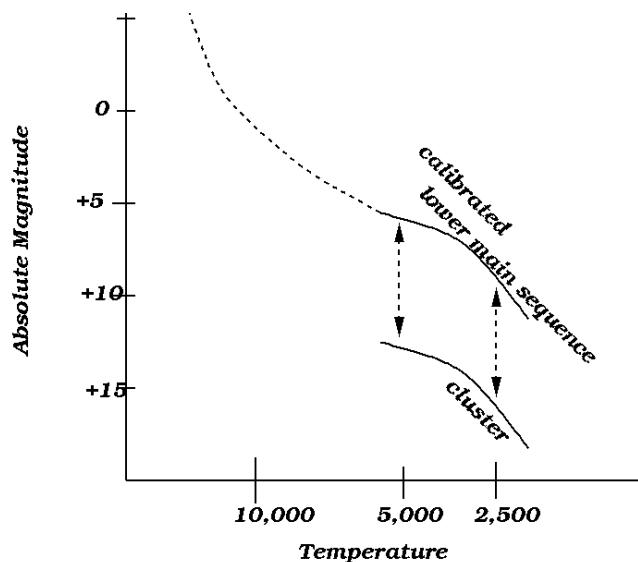

- A star's spectrum → determine spectral type and luminosity class
- A star's position is fixed in H-R diagram → (Vertical) reading of **absolute mag ( $M_v$ )**  
→ Distance can be calculated by  
$$(m-M)_0 = V - M_v - A_v = 5 \log d - 5$$
  
"spectroscopic parallax"
- Observational errors, scatter in the HR diagram → mag uncertainty : **±1.0 mag**  
(distance error : **50%**)

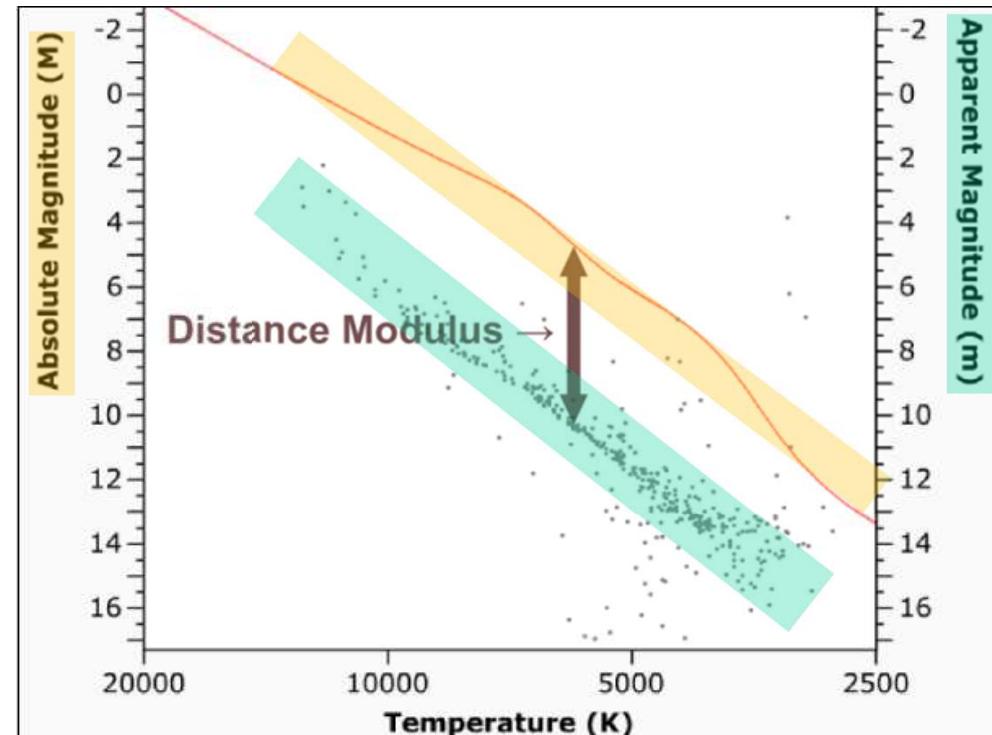

A calibrated H-R diagram

# Spectroscopic parallax – using **spectral type**

- For observational data of an entire star cluster : color – apparent magnitude  
→ shift up and down (in magnitude)
- $(\text{test cluster apparent mag}) - (\text{calibrated absolute mag}) = (m-M)$   
→ distance modulus  
→ same for every star in the cluster
- Better accuracy than the spectroscopic parallaxes → mag uncertainty :  $\pm 0.2$  mag

[https://ned.ipac.caltech.edu/level5/Bothun2/Bothun2\\_3\\_2.html](https://ned.ipac.caltech.edu/level5/Bothun2/Bothun2_3_2.html)

## 2. Pulsating Variable Stars – Cepheids, RR Lyrae

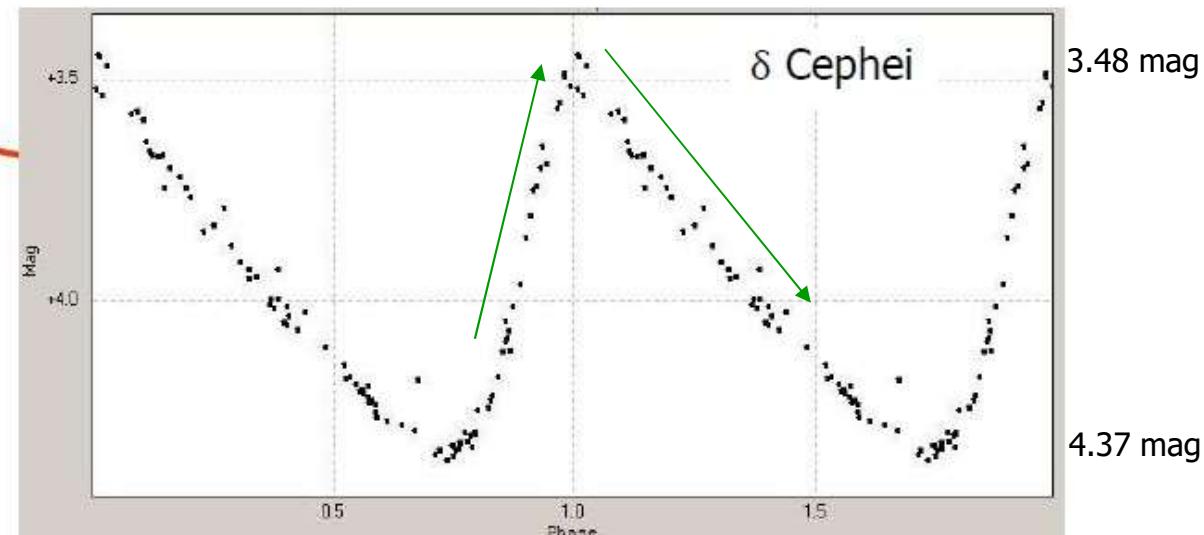

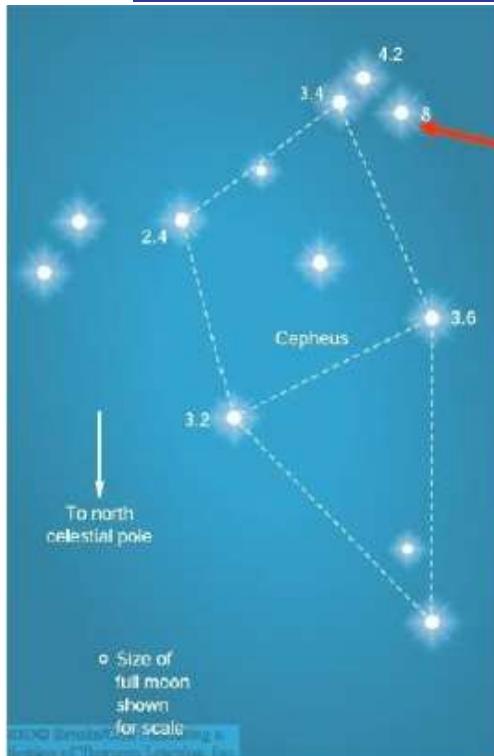

## 2. Pulsating Variable Stars – Cepheids, RR Lyrae

**Figure 1.** Luminosity-effective temperature (or H–R) diagram showing the approximate locations of major pulsating variables coloured roughly by spectral type, the zero-age main sequence and horizontal branch, the Cepheid instability strip, and evolution tracks for model stars of various masses, indicated by small numbers ( $M_{\odot}$ ). Shadings represent opacity-driven p modes (\\\), g modes (//) and strange modes (|||) and acoustically driven modes (≡). Approximate spectral types are indicated on the top axis. Based on figures by Christensen-Dalsgaard and subsequently by Jeffery (2008a).

# Cepheid Variables – Light Curves (LCs)

$P = 5.366341$  d (<http://earthsky.org/brightest-stars/delta-cephei-the-kings-famous-variable-star>)

- =  $\delta$  Cepheids
- = Classical Cepheids
- $M_i \geq 5 M_{\odot}$   
(young stars)  
(in spiral arms)
- Age  $\leq 0.1$  Gyr

Galactic Astronomy (J. Binney & M. Merrifield, 1998) p. 291

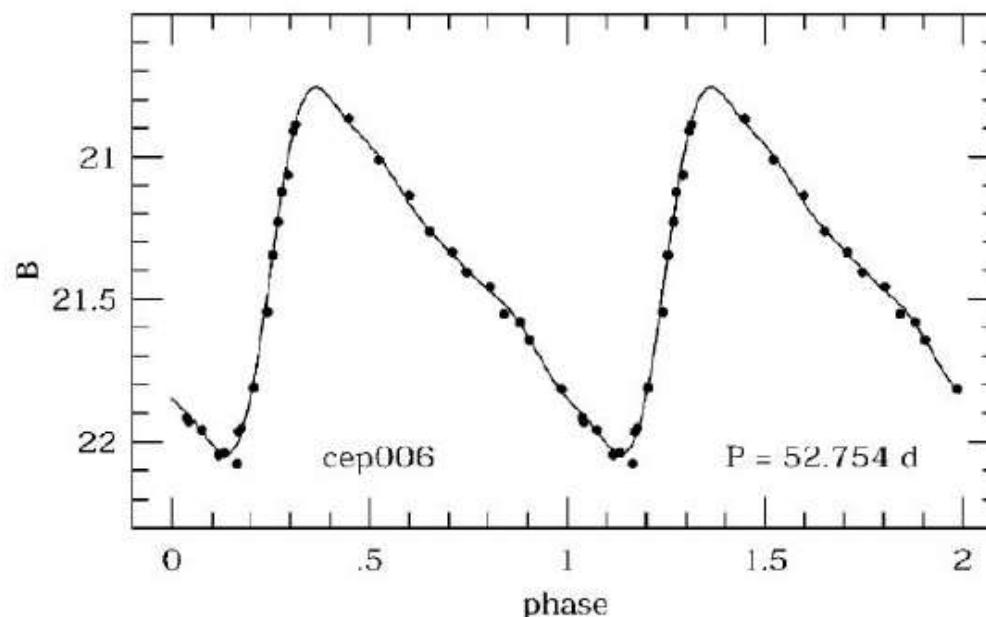

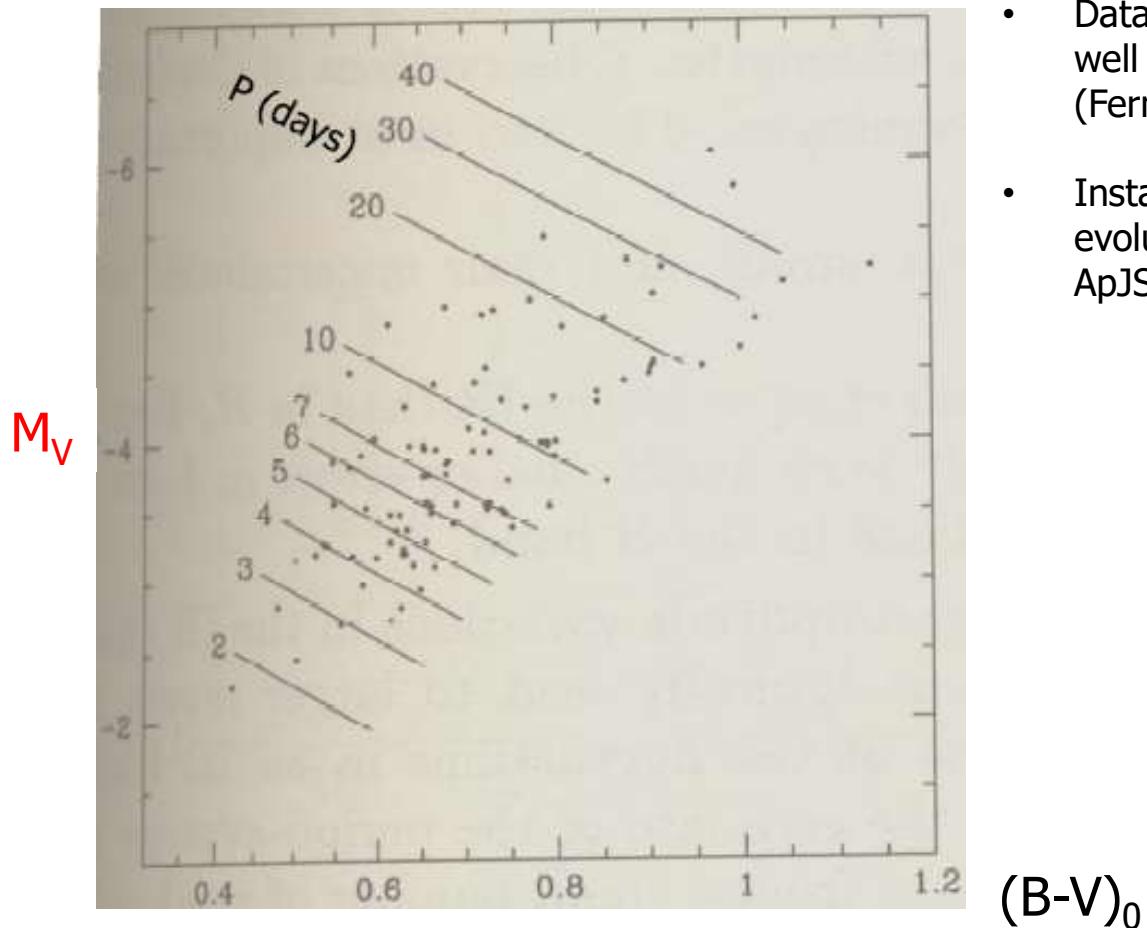

Figure 1: B light-curve of a typical Cepheid in NGC 300. The data were obtained with the ESO-MPA 2.2-m telescope and Wide Field Imager.

# Cepheid Variables

Instability strip (불안정띠)

- Data : 98 Galactic Cepheids with well determined reddening (Fernie 1990 ApJ 354 295)
- Instability strip lines ← stellar evolution models (Chiosi+93 ApJS 86 541)

# Cepheid Variables

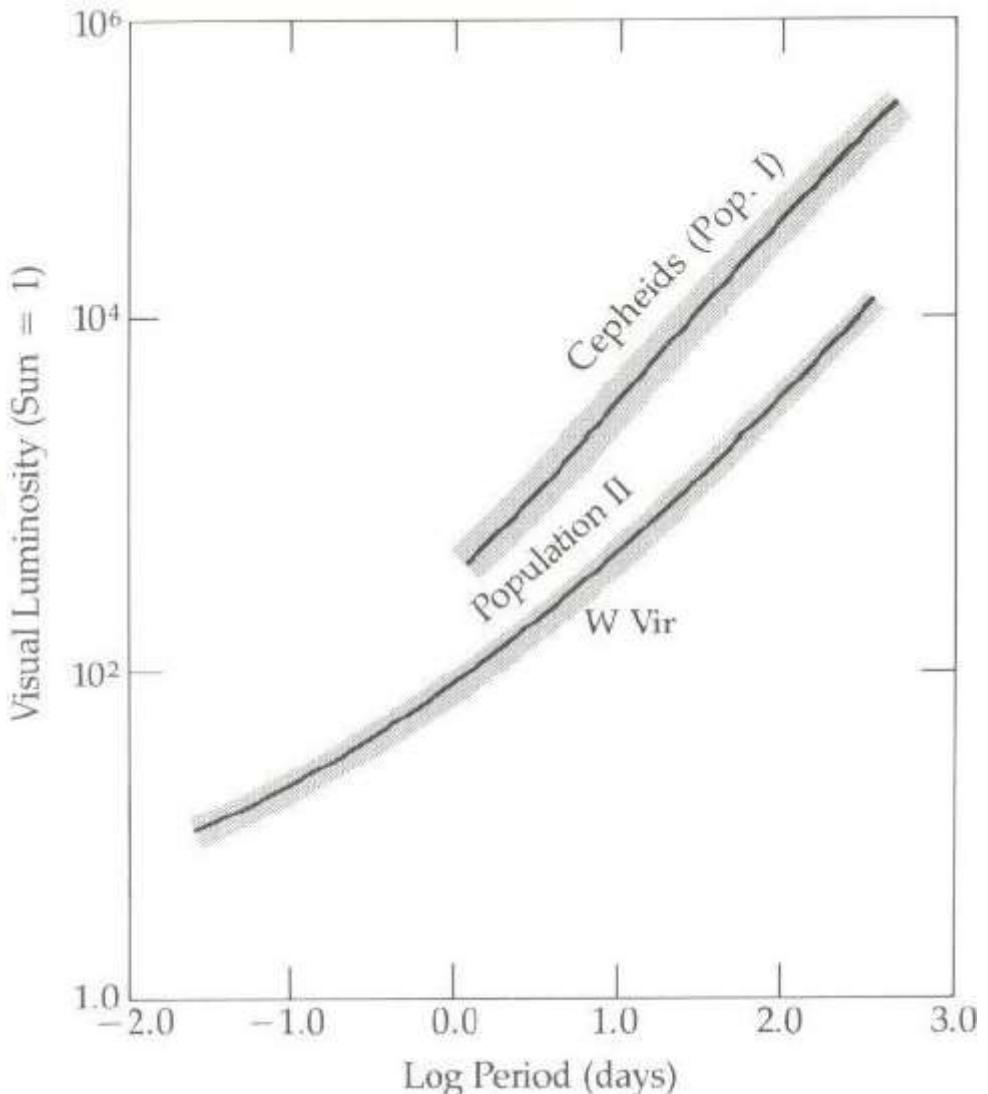

- Periodic (regular) variables
- Pulsation period  $\propto$  median luminosity
- Period-Luminosity relation (**P-L relation**) :  
**Leavitt's law**
- Populations I, II - separate relations
- Classical Cepheids (pop I Cepheids) : more luminous, in spiral arms,  $P = 1 - 50$  d (5-10 d), F6 to K2

$$\langle M_V \rangle = -(2.76 \pm 0.11) \log(P/10\text{d}) - 4.16 \pm 0.05$$

(scatter  $\sim 0.27$  mag)

Galactic Astronomy (J. Binney & M. Merrifield, 1998, p. 292)

- W Virginis Stars (pop II Cepheids) : 4-times less luminous than classical Cepheids, in globular clusters and other population II systems,  $P = 2 - 45$  d (12-20 d), F2 to G6

Henrietta S. Leavitt (1912, Harvard College Obs. Circ., 173, 1 'Discovery of the Cepheid PL relation')

Introductory Astronomy and Astrophysics (4<sup>th</sup> edition)  
Michael Zeilik & Stephen A. Gregory (1998), p. 356

Radcliffe College

# Computer(s)

Harvard College Observatory

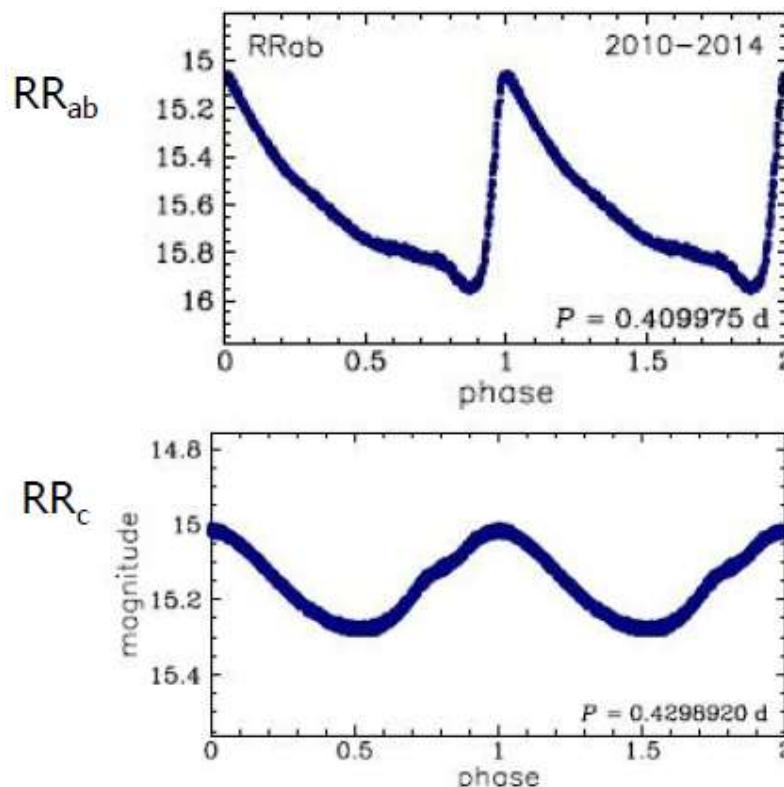

### 3. RR Lyrae stars

- Periodic variable stars
- $P = 1.5$  to  $24$  h ( $\sim 12$  h), Peak  $M_V \sim 0\text{--}1$  mag, spectra A2 to F6
- Current mass  $\sim 0.8 M_\odot$  (original MS mass  $\sim 1 M_\odot$ ), old, relatively metal-poor
- In GCs and in low-metallicity systems (population II) – But, some have high metallicity

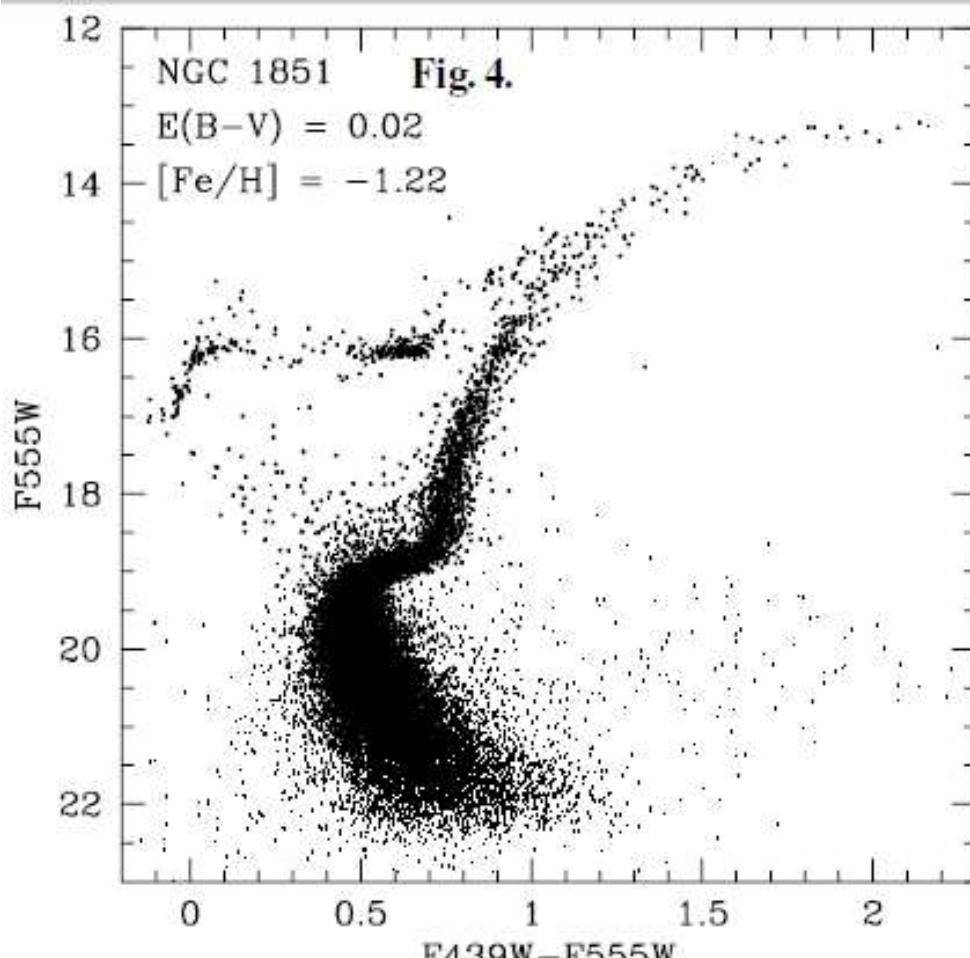

$M_V(RR) = +0.71 \pm 0.12$  at  $\langle [\text{Fe}/\text{H}] \rangle = -1.61$  for the halo (162 stars)

$M_V(RR) = +0.79 \pm 0.30$  at  $\langle [\text{Fe}/\text{H}] \rangle = -0.76$  for the thick disk (51 stars)

## ※ Mass fractions

Mass ratios (rather than numbers of particles)

$$\text{Mass fractions of hydrogen : } X \equiv \frac{\text{total mass of hydrogen}}{\text{total mass of gas}}$$

$$\text{Mass fractions of helium : } Y \equiv \frac{\text{total mass of helium}}{\text{total mass of gas}}$$

$$\text{Mass fractions of metals : } Z \equiv \frac{\text{total mass of metals}}{\text{total mass of gas}}$$

$$X + Y + Z = 1$$

For stars, usually,  $X \sim 0.7$ ,  $0 < Z < 0.03$

$$[\text{Fe}/\text{H}] = \log \frac{(\text{Fe}/\text{H})_*}{(\text{Fe}/\text{H})_\odot} = \log (\text{Fe}/\text{H})_* - \log (\text{Fe}/\text{H})_\odot$$

$$\log Z = 0.977[\text{Fe}/\text{H}] - 1.699$$

$$[\text{Fe}/\text{H}] = 1.024 \log Z + 1.739$$

An Introduction to Modern Astrophysics (2<sup>nd</sup> edition) Bradley W. Carroll & Dale A. Ostlie (1996) p. 325

## 5. Novae (신성) – Rate of Decline

- Peak brightness ( $M_V = -4.8 \sim -8.9$ )
- MMRD (Maximum Magnitude – Rate of Decline) relation  
light from faint novae decays more slowly

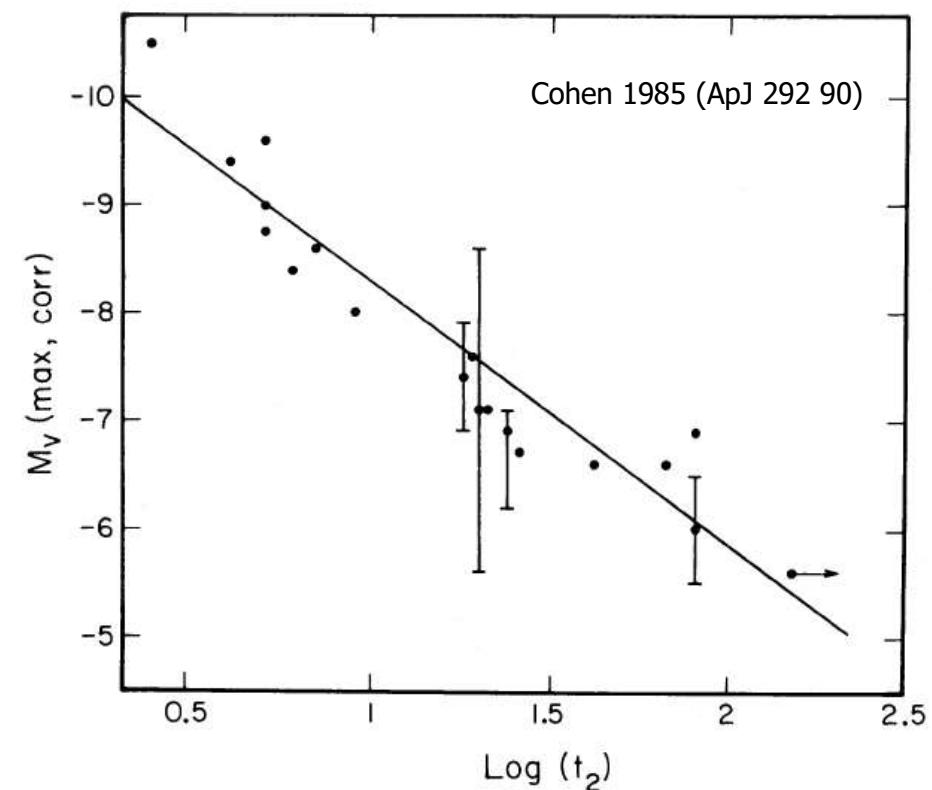

$$M_V(\text{max, corr}) = -10.70(\pm 0.30) + 2.41(\pm 0.23) \log t_2$$

$t_2$  : time that nova takes to decline in brightness by 2 mag from the maximum

Cohen 1985 (ApJ 292 90)

[https://stereo.gsfc.nasa.gov/~thompson/nova\\_sagittarii\\_2012/](https://stereo.gsfc.nasa.gov/~thompson/nova_sagittarii_2012/)

Galactic Astronomy (J. Binney & M. Merrifield, 1998) p. 419

## 6. Supernovae (초신성)

- Brightest objects in galaxies ( $M_V = -14 \sim -22$ )

- Typical types

No H lines (pop II) → Type Ia Ib Ic

WD + Giant/MS/He \*  
(Single Degenerate, SD)

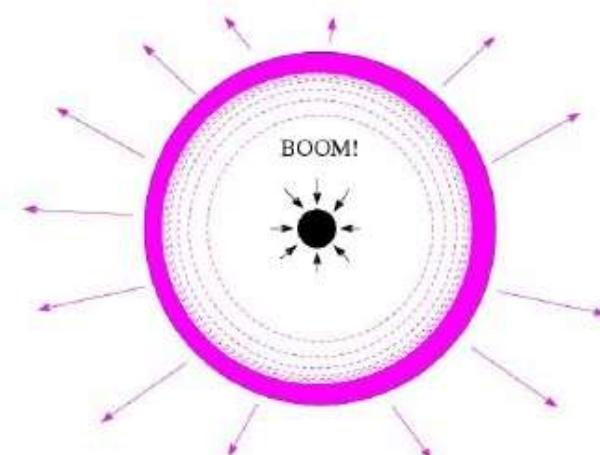

SNe Ia (thermonuclear stellar explosion)  
(WD originated SNe)

백색왜성 기원 초신성

WD + WD  
(Double Degenerate, DD)

H lines (pop I) → Type II

Core collapse

## SN Ia absolute magnitude

---

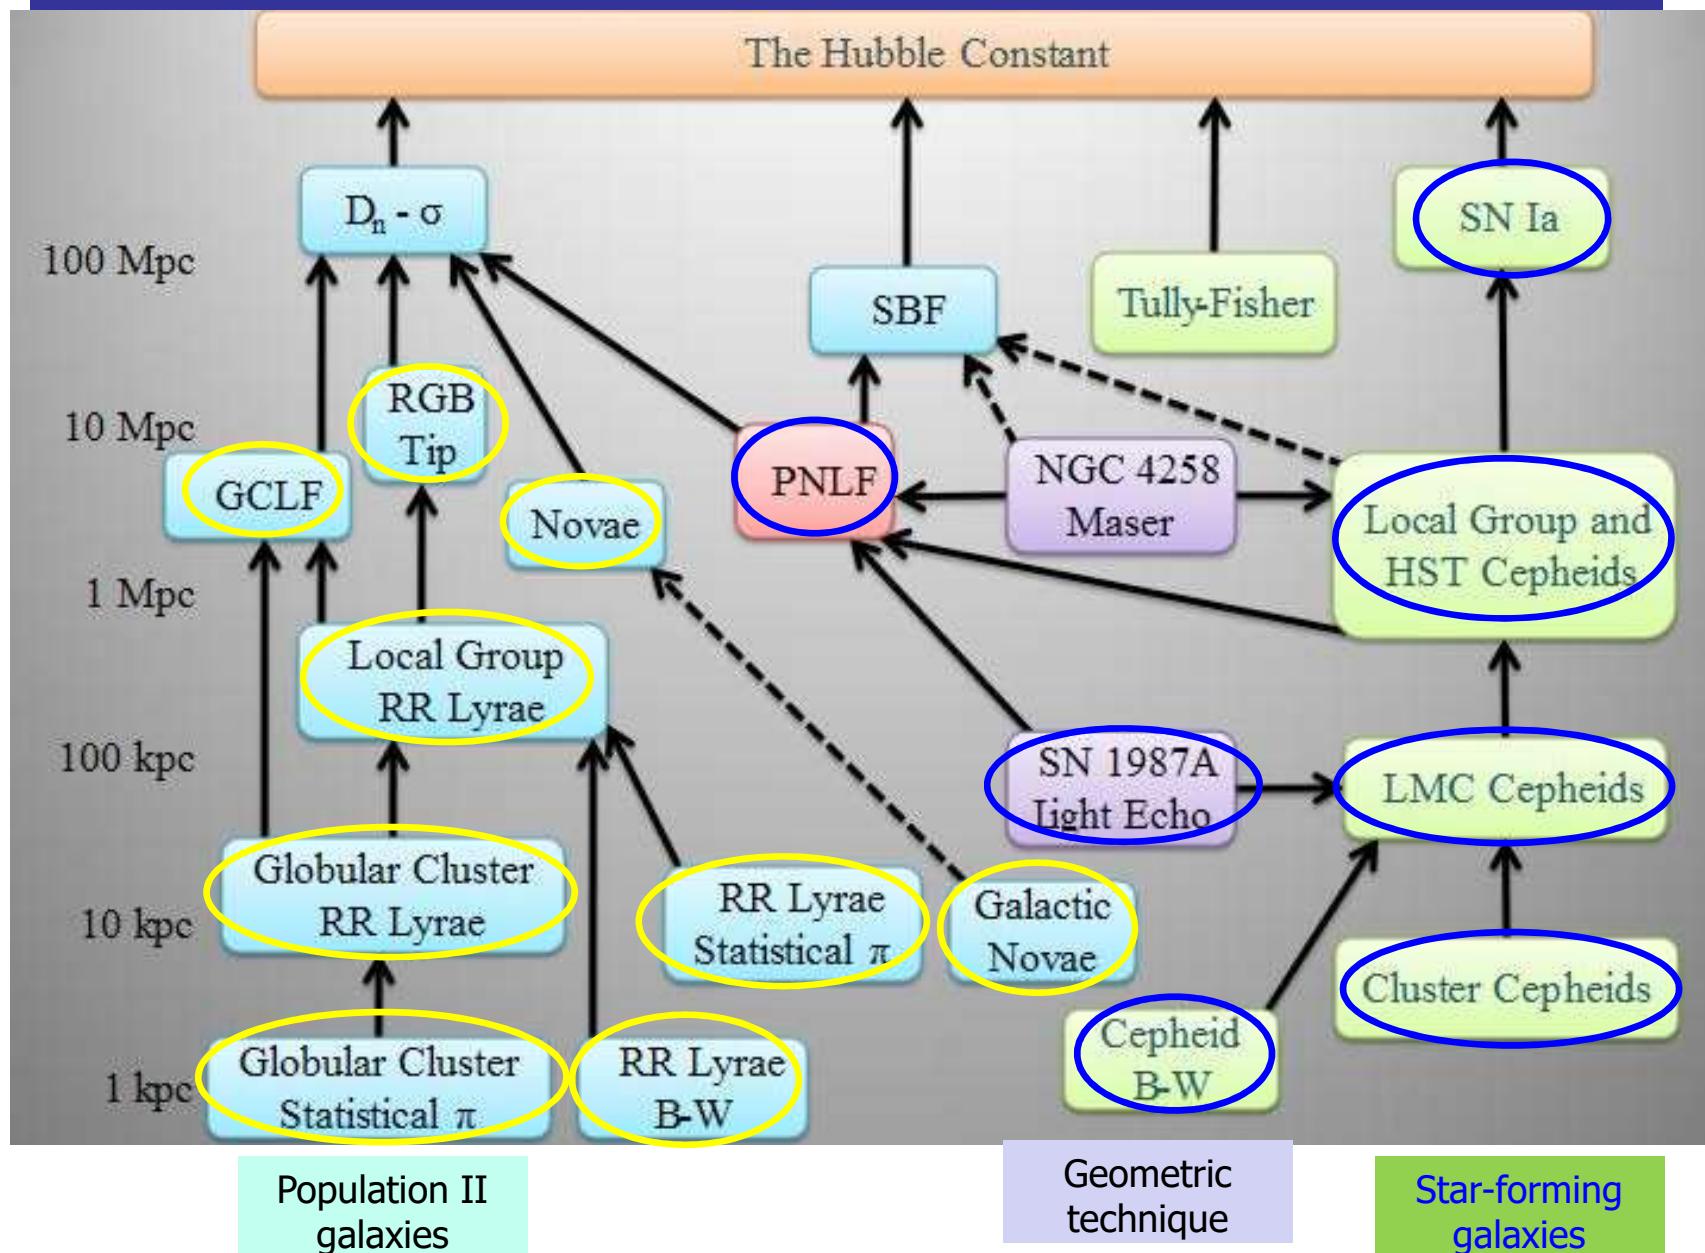

Photometrically, SN Ia rise to maximum light in a period of approximately 20 days (Riess et al 1999b) reaching

$$M_B \approx M_V \approx -19.30 \pm 0.03 + 5 \log(H_0/60) \quad (1)$$

with a dispersion of  $\sigma_M \leq 0.3$  (Hamuy et al 1996b).

explosion models)

# Extragalactic Distance Ladder

# 1. Stars: The Hertzsprung-Russell Diagram (항성: HR도)

## 1.3 Magnitudes (등급)

<http://www.centauri-dreams.org/?p=11322>

<http://www.centauri-dreams.org/wp-content/uploads/2010/02/light-candles.jpg>

# 1. Magnitude scale

$$m - n = 2.5 \log\left(\frac{l_n}{l_m}\right)$$

→ apparent magnitude (겉보기등급, 실시등급)

- $m > n \leftarrow l_n > l_m$
- Brighter objects : numerically smaller magnitudes

## Absolute magnitude, Distance modulus

- A very luminous star appears dim – if far away
- A low-luminosity star look bright – if very close  
→ distance links fluxes and luminosities
- **absolute magnitude** (절대등급) = the magnitude to be observed if the star is placed at a distance of **10 pc** from the Sun → capital M

$$\frac{L}{l} = \left(\frac{d}{D}\right)^2 = \left(\frac{d}{10}\right)^2$$

- $M - L, m - l$

$$m - M = 2.5 \log\left(\frac{L}{l}\right) = 2.5 \log\left[\left(\frac{d}{10}\right)^2\right] = 5 \log\left(\frac{d}{10}\right)$$

Extinction corrected

$$(m - M)_0 = 5 \log d - 5 \quad \text{distance modulus}$$

$$m - M = 5 \log d - 5 + A \quad V - M_V = 5 \log d - 5 + A_V$$

## 2. Photometric Filter Systems (측광계)

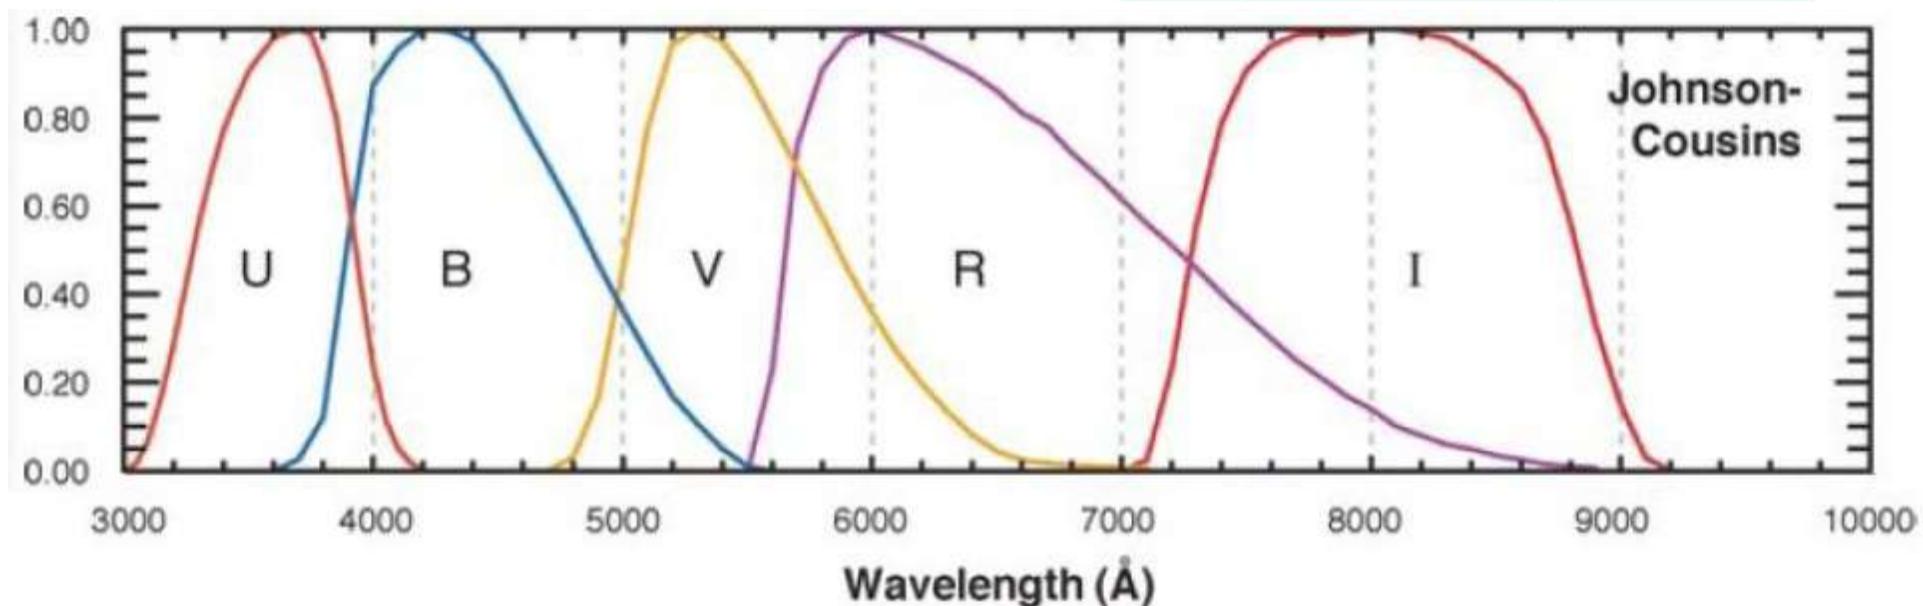

### ➤ Johnson-Cousins UBVRI System

- Originally defined by Johnson & Morgan (1953) : UBV
- Extended by Cousins (1974) : UBVRI
- Re-analyzed by Bessell (1990)

$$366 \text{ nm} =$$

$$\begin{aligned}1 \text{ nm} &= 10^{-9} \text{ m} \\1 \text{ \AA} &= 10^{-10} \text{ m} \\1 \text{ nm} &= 10\text{\AA}\end{aligned}$$

	Effective Wavelength ( $\lambda_{\text{eff}}$ )	Bandpass ( $\Delta\lambda$ )
U	3663 Å	650 Å
B	4361 Å	890 Å
V	5448 Å	840 Å
R	6407 Å	1580 Å
I	7980 Å	1540 Å

## 2. Photometric Filter Systems (측광계)

---

Bandwidth :

Broadband :  $\Delta\lambda < 1000 \text{ \AA}$  (광대역)

Intermediate band :  $70 \text{ \AA} < \Delta\lambda < 400 \text{ \AA}$  (중대역)

Narrowband :  $\Delta\lambda < 70 \text{ \AA}$  (협대역)

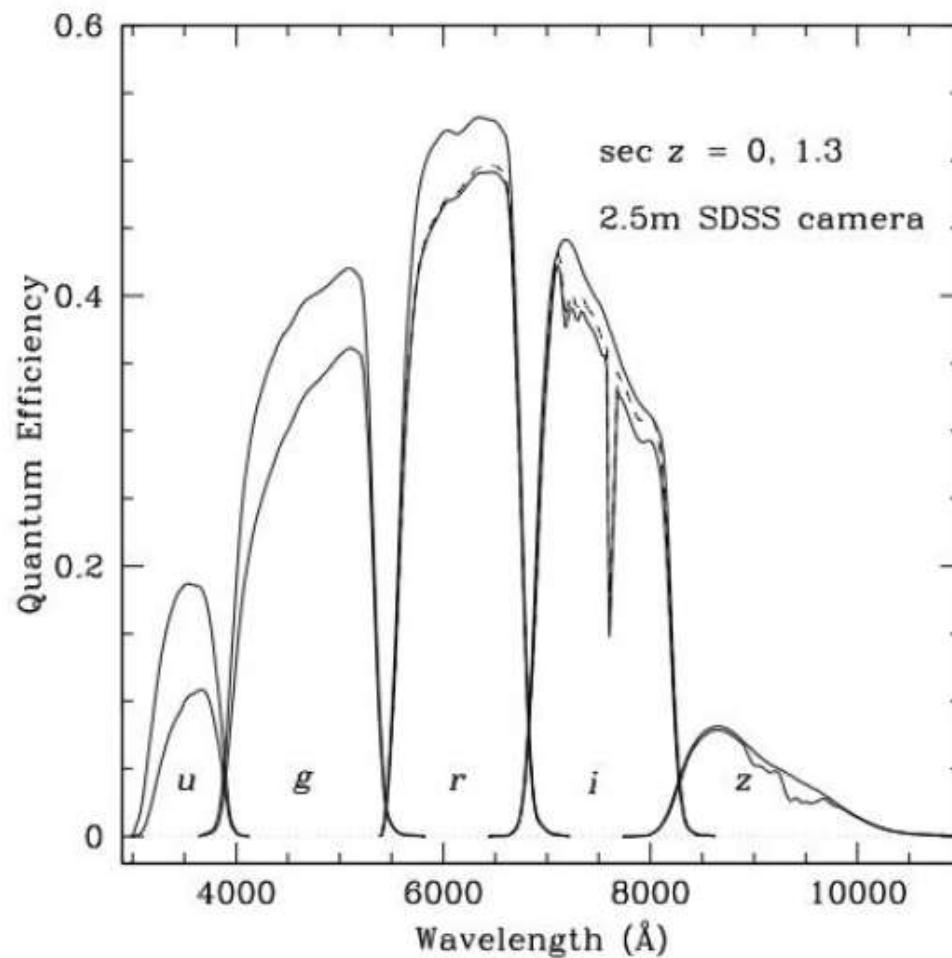

## 2. Photometric Filter Systems (측광계)

➤ Sloan Digital Sky Survey (SDSS) System

- ugriz

TABLE 19  
SDSS FILTER PARAMETERS

Name	$\lambda_{\text{eff}}$ (Å)	$\sigma^2$	FWHM (Å)	$Q$
$u$ .....	3551	$3.00 \times 10^{-3}$	581	0.0171
$g$ .....	4686	$7.13 \times 10^{-3}$	1262	0.0893
$r$ .....	6166	$3.13 \times 10^{-3}$	1149	0.0886
$i$ .....	7480	$2.58 \times 10^{-3}$	1237	0.0591
$z$ .....	8932	$3.18 \times 10^{-3}$	994	0.0099

### 3. Color Index (CI, 색지수, 색)

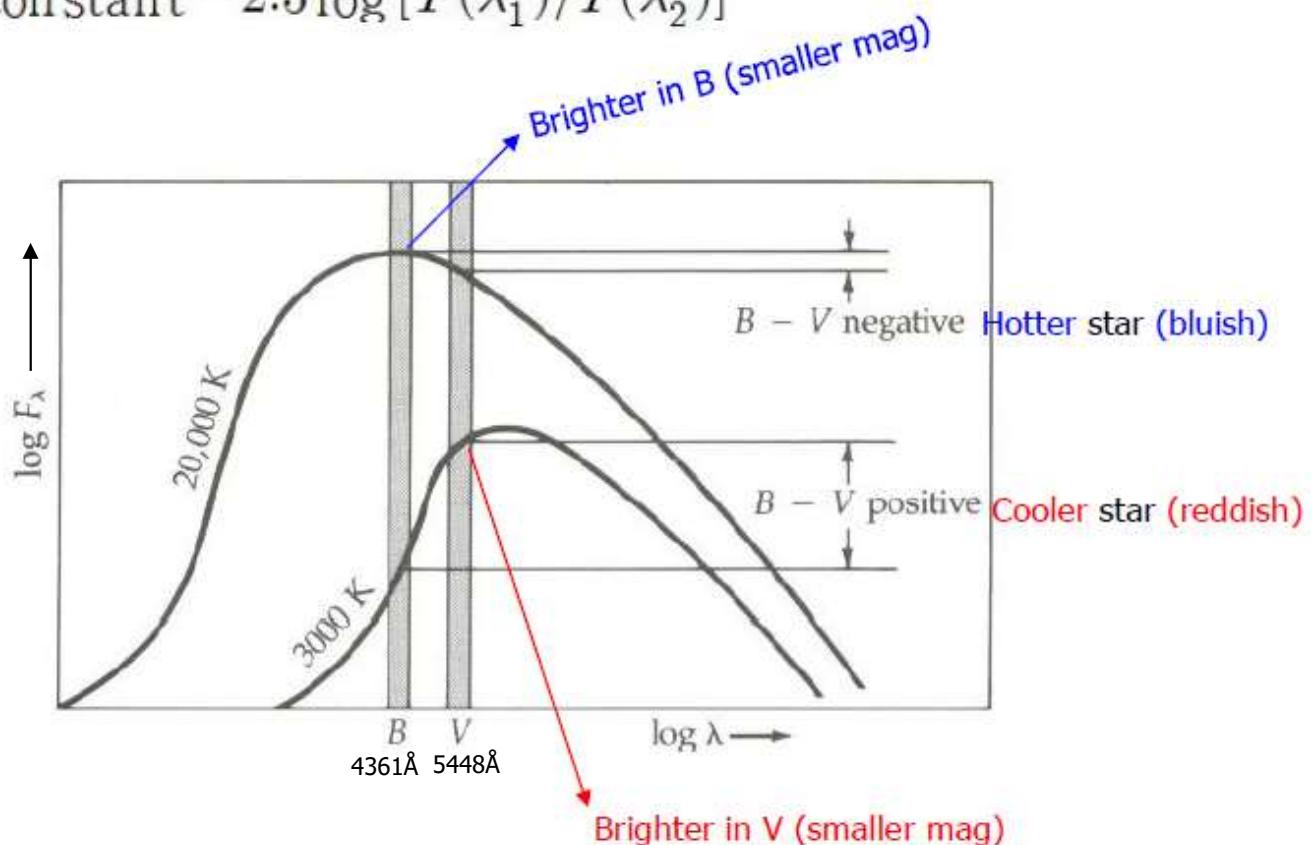

- Color index = difference between magnitudes at two different effective wavelengths

$$CI = m(\lambda_1) - m(\lambda_2)$$

- Mag difference  $\rightarrow$  flux ratio at the specific wavelengths involved

$$CI = \text{constant} - 2.5 \log [F(\lambda_1)/F(\lambda_2)]$$

- Hotter stars (bluish) : negative CI
- Cooler stars (reddish) : positive CI

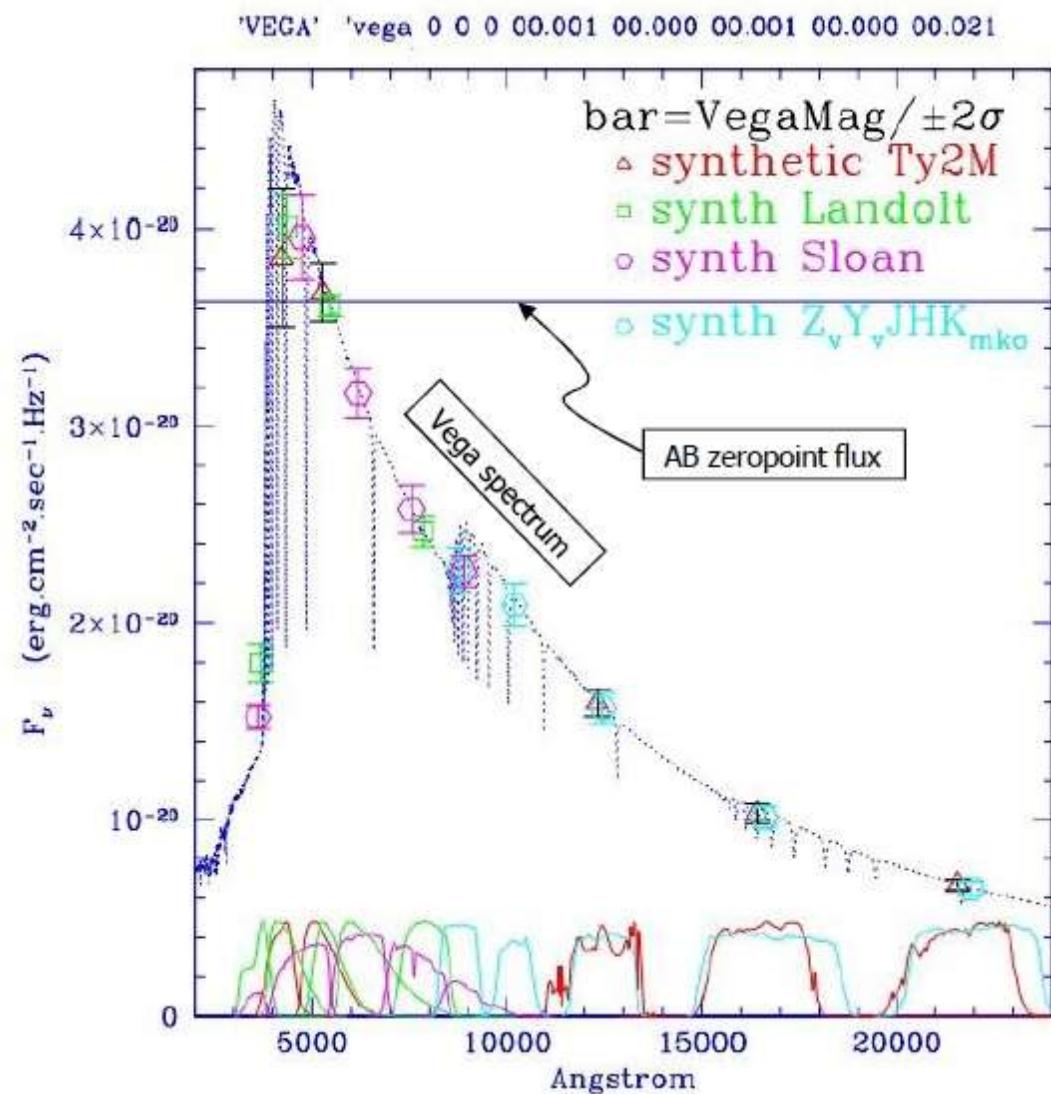

# Magnitude systems

## ➤ Vega magnitude system

- Vega ( $=\alpha$  Lyr) : the primary calibrating star
- Surface temperature = 10,000 K
- CI = 0
- Zero-point was defined in terms of unreddened main-sequence (MS) stars of class A0 ... with an accuracy sufficient to permit the placement of the zero-point to about 0.01 mag

## ➤ AB magnitude system

- Magnitude zero point corresponds to a flux density of 3631 Jy (1 Jy = 1 Jansky =  $10^{-26}$  W Hz $^{-1}$  m $^{-2}$  =  $10^{-23}$  erg s $^{-1}$  Hz $^{-1}$  cm $^{-2}$ )

Pickles & Depagne (2010 PASP 122 1437)

- Bessell (2005, ARA&A, 43, 293 – Standard photometric systems)
- Casagrande & Vandenberg (2014, MNRAS, 444, 392 – Synthetic stellar photometry. I. General considerations and new transformations for broad-band systems)

## 4. Color Excess, Bolometric Magnitude

- Interstellar dust grains absorb and scatter starlight
- Observed light gets faint (**extinction**) and appears redder (**interstellar reddening**)  
(소광) (성간적색화:  $\lambda$ -dependent)

- **Color Excess** (색초과) = observed color – intrinsic color

$$E(B-V) = (B-V) - (B-V)_0$$

- **Interstellar extinction** :

$$A_V \sim R \times E(B-V), \quad R = 3.0, 3.1, 3.2, 3.3$$

R : total-to-selective extinction ratio

- ← • Amount of interstellar medium (ISM)  
• ISM composition  
• Galactic longitude

- **Bolometric magnitude** (복사등급) : total rate of energy output at all wavelength

$$l_{bol} = \int_0^{\infty} l_{\lambda} d\lambda$$

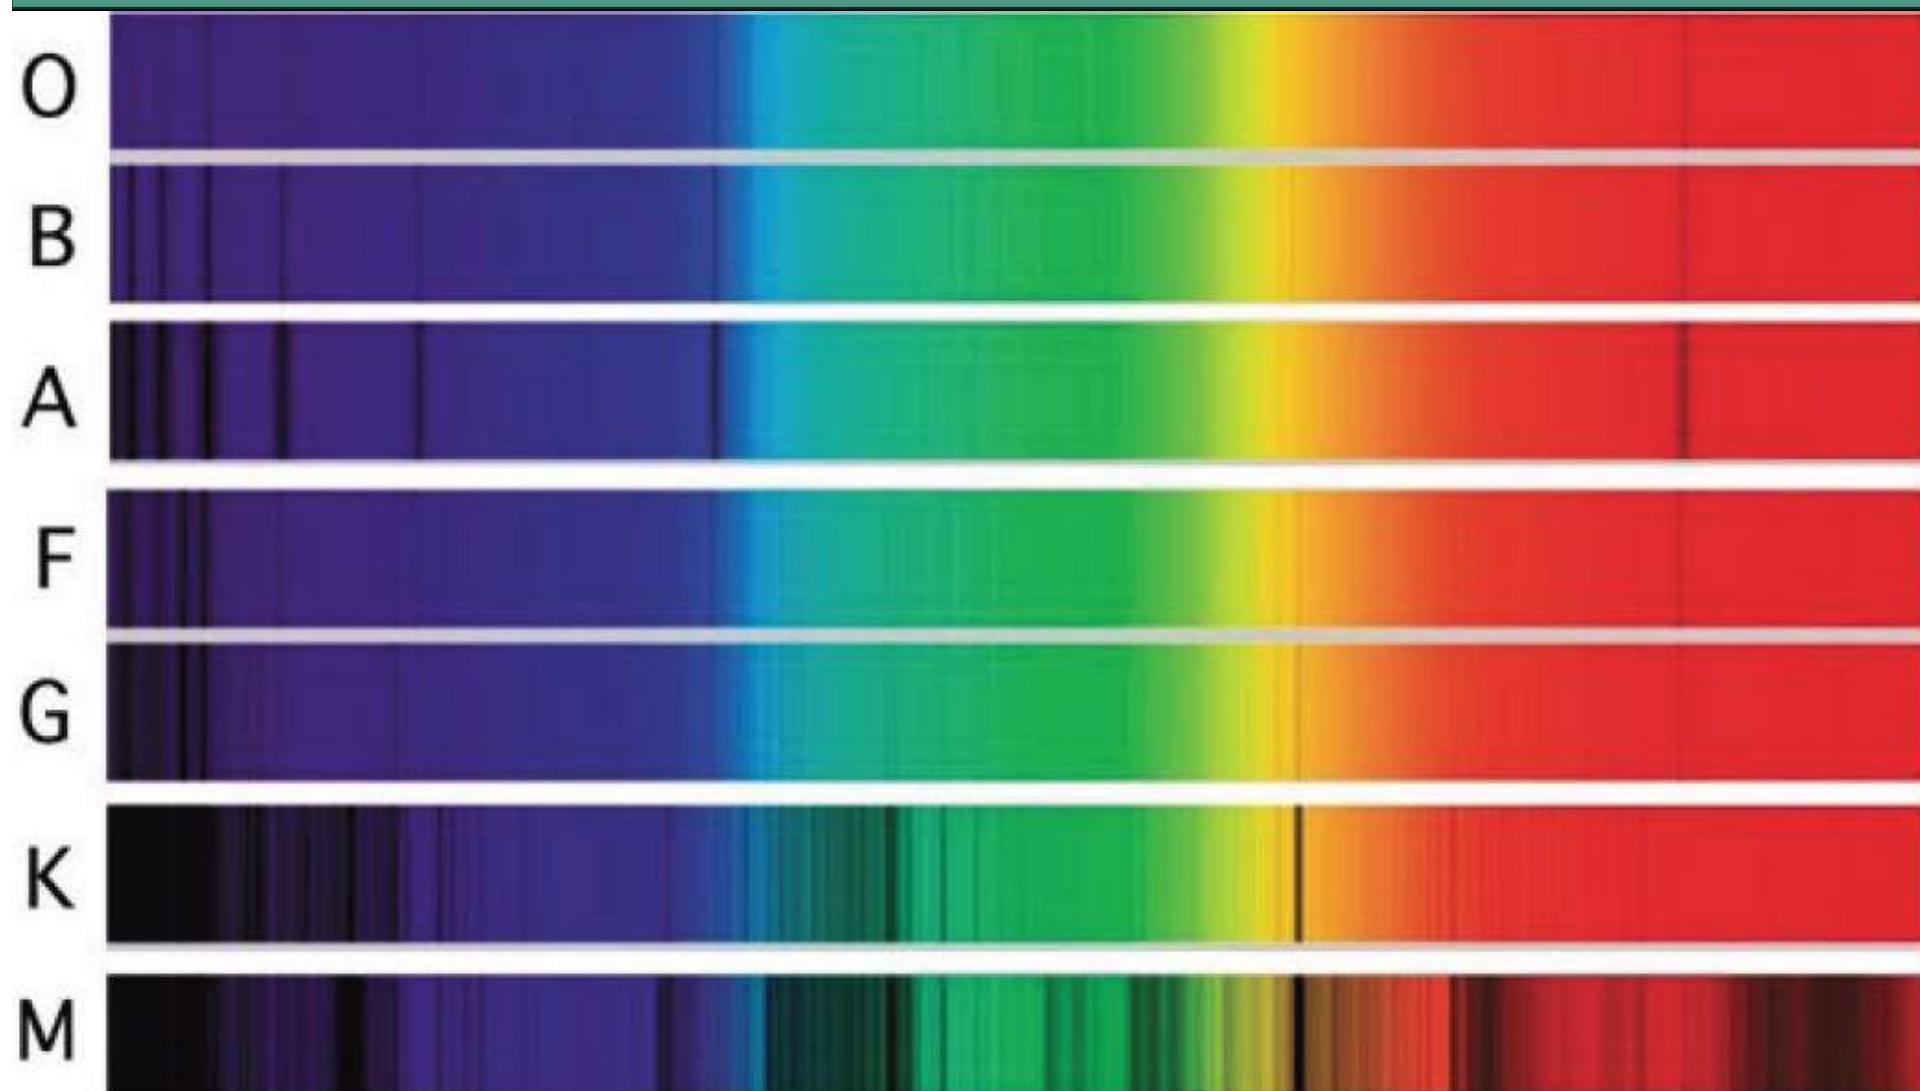

- **Bolometric correction (BC, 복사보정)** : difference between the bolometric and visual magnitudes

$$BC = m_{bol} - m_v = M_{bol} - M_v = 2.5 \log \left( \frac{l_v}{l_{bol}} \right)$$

for the Sun (G2) : BC = -0.07

Girl(Guy),  
Kiss Me!

O0, O1, O2, ...O9,      B0, B1, B2, ...B9, ...

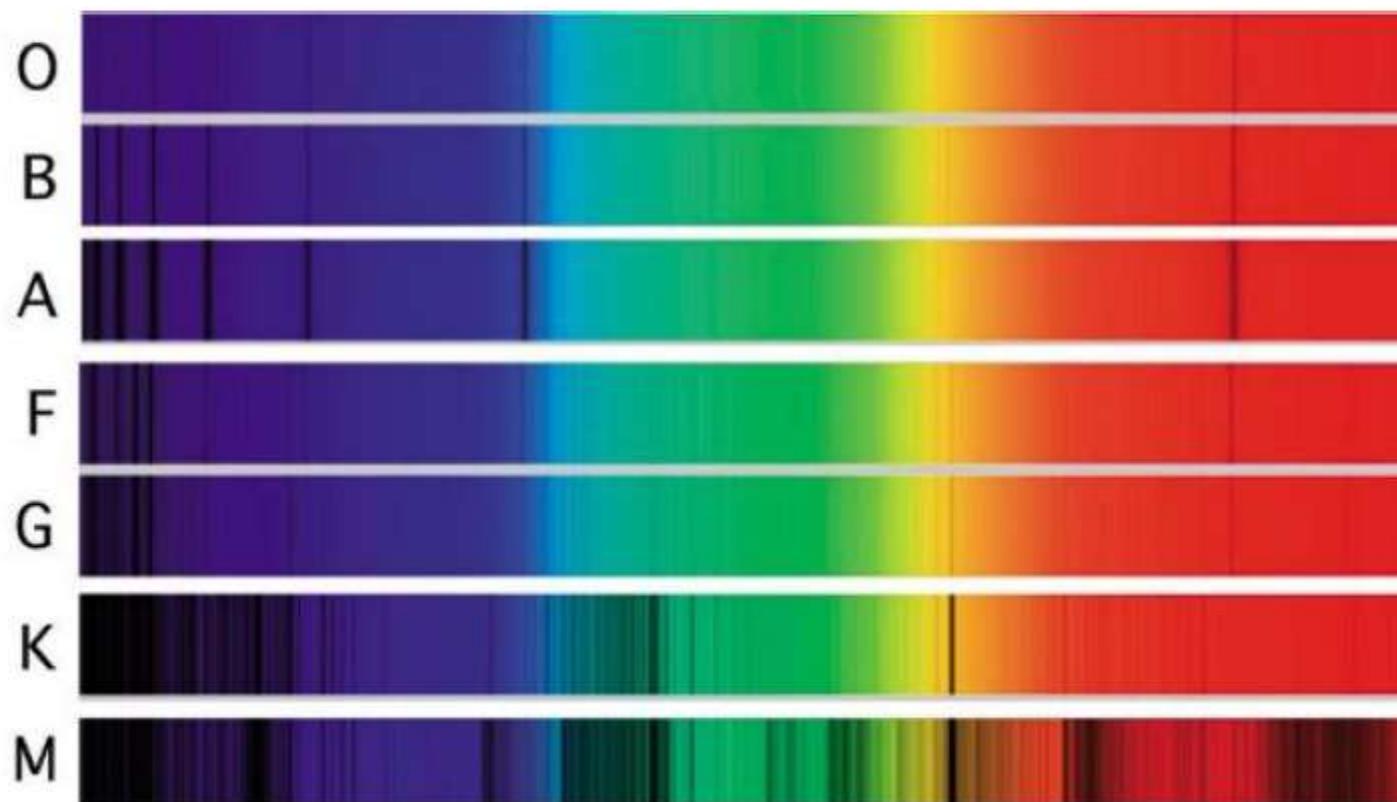

# Stellar spectra

---

Stars' spectra : differ depending on T and composition

Early-types (O and B) stars – few spectral lines

Late-types (K and M) stars – many spectral lines

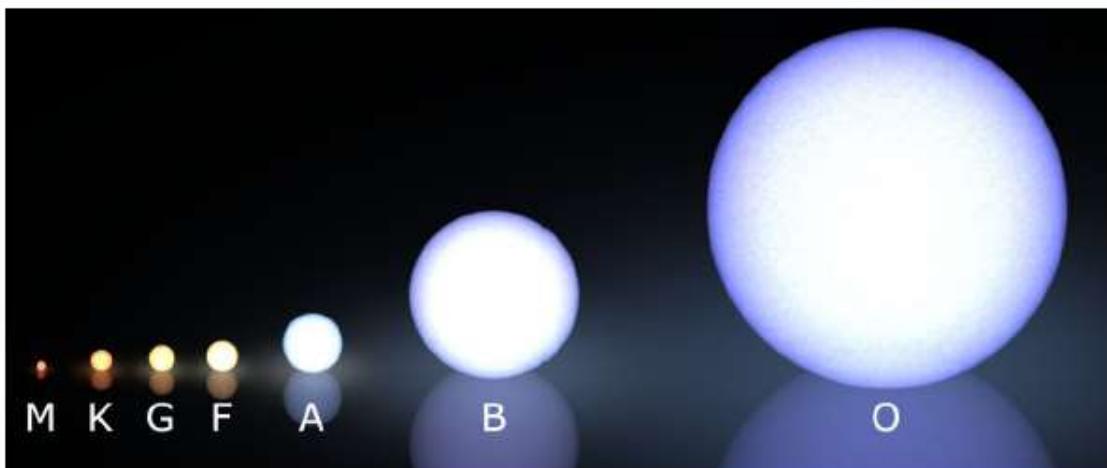

# Spectral types

Spectral type	Stars	Spectral features	(e.g.)
O	blue stars, usually SGs, very luminous and hot, rare	<b>He II absorption lines</b> (sometimes emission: 4541, 4200Å); He I lines (4471, 4026Å) weak but increasing in strength from O5 to O9; lines from highly ionized species (e.g., C III, N III, O III, Si IV); H lines prominent but relatively weak; strong UV continuum	$\zeta$ (Zeta) Puppis (O4 I)
B	blue white stars, mainly giants	<b>Strong He I lines, maximum at B2</b> ; no He II lines; <b>H absorption lines strengthening from B0 to B9</b> ; lower-excitation ions (e.g., C II, O II, Mg II, Si II, Si III)	Rigel (= $\beta$ Orionis, B8 Ia), $\epsilon$ Ori (B0 Ia)
A	White stars, dwarfs to giants	<b>H absorption lines maximum strength at A0</b> and decrease towards later types; <b>ionized metal lines (Fe II, Mg II, Si II) at max strength near A5</b> ; Ca II weak and increase in strength; lines of neutral metals appear weakly	Sirius (A1 V), $\alpha$ Lyr (=Vega, A0 V)
F	yellow white stars, mainly dwarfs	H absorption lines weakening rapidly, <b>Ca II H&amp;K absorption lines strengthen</b> ; lines of neutral metals (Fe I, Cr I) and first ionization states of metals appear prominently	Procyon (= $\alpha$ CMi, F5 IV-V)
G	yellow stars, mainly dwarfs	Solar-type spectra; <b>Ca II absorption lines dominate (max near G2)</b> ; neutral metal lines (Fe I, Mn I, Ca I) strengthening; ionized metal lines diminish; <b>G band (CH) strong</b> ; H lines very weak	Sun (G2 V)
K	orange stars, can exist as giants and dwarfs	<b>Neutral metallic absorption lines dominate</b> ; <b>Ca lines strong</b> ; H lines almost gone; molecular bands (CH, CN, TiO) developing; continuum weak in blue	Arcturus (= $\alpha$ Boötis, K0 III), Aldebaran (= $\alpha$ Tau, K5 III)
M	red stars, exist at extremes either giants or red dwarfs	Strong <b>molecular bands, particularly TiO by M5</b> ; <b>neutral metallic absorption lines</b> (e.g., quite strong Ca I); red continuum	Betelgeuse (= $\alpha$ Orionis, M2 I), Proxima Centauri (M5.5 V)

# Spectral types

Spectral type	Stars	Spectral features	(e.g.)

## C (carbon) stars

- giant stars with similar temperatures of G, K, M stars ( $T = 3100 - 4600$  K)
- different compositions : C is overabundant relative to O

hotter R stars ( $C_2$ , CN bands)

cooler N stars ( $C_2$ , CN, CH bands, little TiO)

S stars : molecular bands of the heavy-metal oxides ZrO, LaO, YO (instead of TiO)

: enhanced CN absorption bands

: neutral atoms strong as in K and M types

Galactic Astronomy (J. Binney & M. Merrifield, 1998) p. 92

Introductory Astronomy and Astrophysics (4<sup>th</sup> edition) Michael Zeilik & Stephen A. Gregory (1998), p. 266

$^{22}_{\text{Ti}}{}^{48}$	: Titanium
$^{39}_{\text{Y}}{}^{89}$	: Yttrium
$^{40}_{\text{Zr}}{}^{91}$	: Zirconium
$^{57}_{\text{La}}{}^{139}$	: Lanthanum

R Sculptoris : a sample C star  
(Maercker+12, Nature, 490, 232)

# Extended spectral types

- Cool red dwarfs and brown dwarfs (BDs) - Infrared spectra
- BD : objects whose central temperatures never reach the critical threshold for stable thermonuclear burning (Kirkpatrick + 11 ApJS 197, 19  
'The first hundred BDs discovered by the Wide-field Infrared Survey Explorer (WISE)')
- BDs cool as they age : from M to L, T, Y type  
The less massive, the faster cooling
- Class L : mostly BDs with substellar mass, some stars with H-fusion  
(e.g.) V838 Mon
  - Temp  $\sim 1,700$  K ( $\sim 1,400$  °C)
  - M and L types = mixture of stars and BDs

J. D. Kirkpatrick (2005, ARA&A, 43, 195 'New spectral types L and T')

L dwarf - artist's impression

V838 Monocerotis – HST  
[https://en.wikipedia.org/wiki/V838\\_Monocerotis](https://en.wikipedia.org/wiki/V838_Monocerotis)

# Extended spectral types

---

- **Class T**

cool brown dwarfs

surface  $T \sim 1,200 \text{ K}$  ( $1,000 - 1,600 \text{ K}$ )  
 $(\sim 900 \text{ }^\circ\text{C})$  ( $700 - 1,300 \text{ }^\circ\text{C}$ )

prominent **methane ( $\text{CH}_4$ )** in the spectra  
→ "methane dwarfs"

T dwarfs would appear **reddish, or magenta**, to the eye.

T dwarf - artist's impression

# Extended spectral types

---

- Class Y

BDs cooler than class T

(coldest BDs, latest classification letter)

Cushing + 11 (ApJ, 743, 50 'The discovery of Y dwarfs using data from the Wide-field Infrared Survey Explorer (WISE)')

Temp  $\sim 298 - 448$  K (25 – 175 °C)

Mass :  $9 - 25 M_J$

N = 17 (2013 August)

mostly nearby : 9 – 40 ly

(WISE 1541-2250, d~9 ly : 7<sup>th</sup> closest star system)

not detected at visible wavelengths

Kirkpatrick + 13 (ApJ, 776, 128 'Discovery of the Y1 dwarf J064723.23-623235.5')

## Extended spectral types

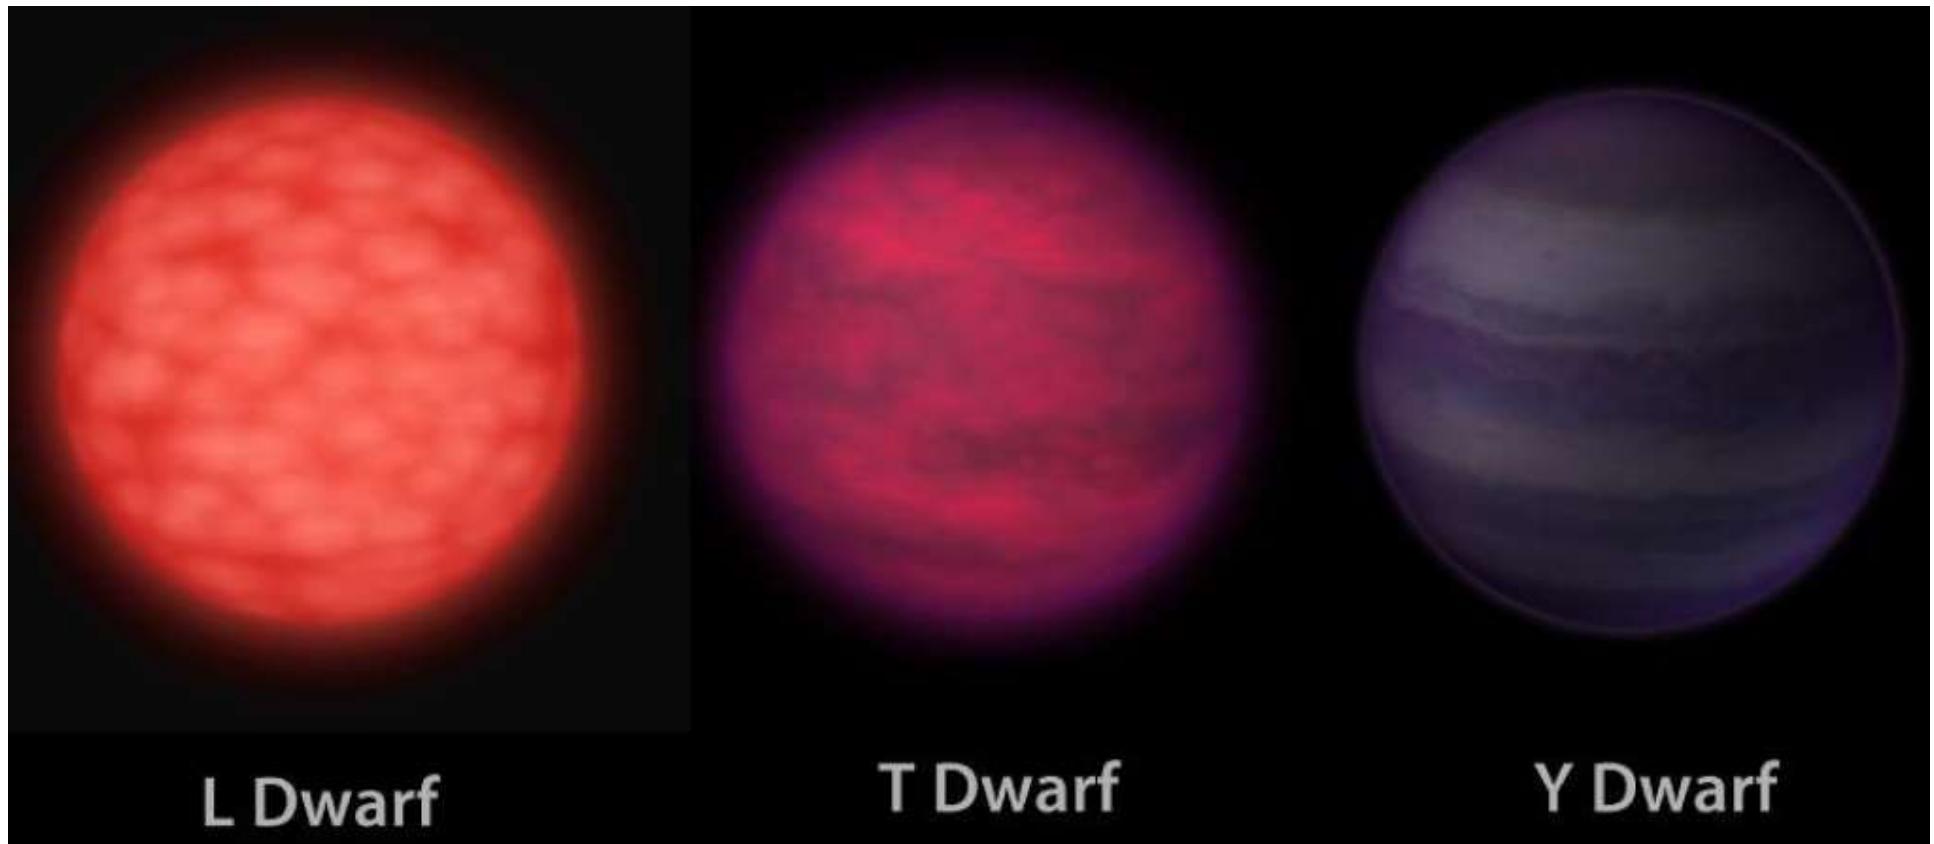

- WISE (Wide-field Infrared Survey Explorer) → found ~100 new BDs → 6 Y stars
- Coldest : **WISE 1828+2650, T~300 K (25°C)**

Y dwarf **WISE 1828+2650**  
- artist's impression  
- purple color choice : artistic reason
