2. The Evolution of Stars (별의 진화) 2-1 Energy Generation (에너지 생성)

Hydrostatic equilibrium (정 유체역학적 평형)

https://pages.uoregon.edu/jimbrau/BraulmNew/Chap16/FG16_06.jpg

김상철 (Sang Chul KIM)

Main Sequence (MS, 주계열성)

- Nuclear fusion (proton-proton chain, 양성자-양성자 연쇄반응) → energy generation and radiation
- Mass decreases slowly → almost constant luminosity (equilibrium between pressure and gravity)
- core: N(H) decreases, N(He) increases
- M > 1.5 M $_{\odot}$, T_{center. \odot} > 1.5 × 10⁷ K \rightarrow H burning by CNO cycle (탄소 순환반응)

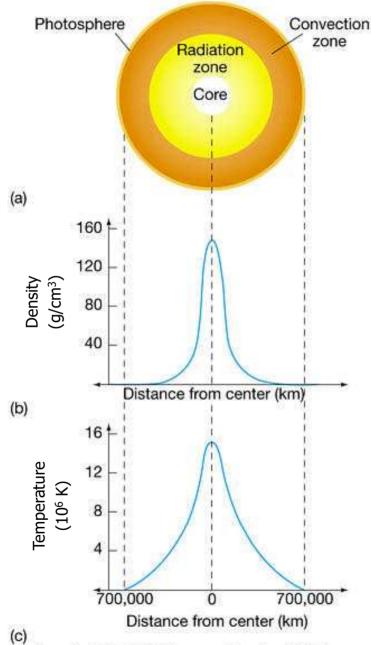

Hydrostatic equilibrium (정 유체역학적 평형)

• If somehow core H-burning accelerates \rightarrow Core T \uparrow , P \uparrow \rightarrow star expands

Expansion makes T ↓ → H-burning decelerates

Hydrostatic equilibrium makes H-burning speed keep ~constant

Interior structure of the Sun (태양의 내부 구조)

Why H-burning occurs at the core - 1

Low temperature: small speeds

Low Temp: small speeds

→ mutual Electrical repulsion > proton-proton fusion

Why H-burning occurs at the core - 2

High temperature:
large speeds

+

High Temp: large speeds

→ Nuclei able to get close enough for strong nuclear force

(강한 핵력) to act

→ Nuclei fuse & energy released

symbol

$${}_{Z}^{A}X$$

X: the chemical symbol of the element (e.g.: H, He, ...)

Z: the number of protons (the total positive charge, in units of e)

A: the mass number (the total number of nucleons, protons plus neutrons)

A = Z+N
 (mass number = Z protons + N neutrons)

$$^{(e.g.)}_{1}H$$
 $^{4}_{2}He$

```

          4 H \rightarrow 4.0312
          1 He \rightarrow 4.0026
          \trianglem = 0.0286 (mass deficit/defect, 질량 결손)
\triangle m = 4 \times m(p) - m(He)
       = (0.0286 \times 1.67 \times 10^{-24} \text{g}) \times (3 \times 10^{10} \text{ cm/s})^2
       = 4.3 \times 10^{-5} \text{ erg}
       = 4.3 \times 10^{-12} J
                                          1 Joule = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2
                                          = 1 N·m
                                          = 10^7 \text{ erg}
                                          = 6.24 \times 10^{18} \text{ eV}
                                                                                                                             Released
                                          = 0.2390 cal
                                                                                                                               energy
                                          = 2.78 \times 10^{-7} \text{ kW} \cdot \text{h}
```

4 protons

1 He nucleus (2 protons +

2 neutrons)

- Energy from coal 1 kg \sim 5000 kcal = 2.1 \times 10⁷ J
- Use H 1 kg to produce He
 - → 0.993 kg He produces, 0.007 kg changes into E

$$\rightarrow$$
 E = mc² = 7 g × (3 × 10¹⁰ cm/s)² = 7 × 9 × 10²⁰ g cm²/s²
= 6.3 × 10²¹ erg = 6.3 × 10¹⁴ J

 \rightarrow same as E from 3 \times 10⁷ kg = 30,000 tons of coal

Sun : 4×10^{38} protons/sec = 6.68×10^{14} g/sec are consumed. 2×10^{38} neutrinos/sec are generated.

Sun : $1 L_{\odot} = 3.9 \times 10^{33} \text{ erg/s} = 3.9 \times 10^{26} \text{ J/s}$

$$1 L_{\odot} = 3.9 \times 10^{33} \, \text{erg/s} = 3.9 \times 10^{26} \, \text{J/s}$$

= amount of electricity for all human beings can use for 10^7 years

Assuming:

Mankind populations = $5 \times 10^9 \rightarrow 10^9$ families (assume 1 family = 5 members)

Monthly family electricity uses, home use: 200~250 kW·h

Let's assume ~1000 kW·h/month including commercial use, etc

 $= 10^6 \text{ W} \times 3600 \text{ s/month} = 10^6 \text{ J/s} \times 3600 \text{ s/month} = 3.6 \times 10^9 \text{ J/month}$

$$1 W = 1 J/s$$

Monthly mankind electricity uses $\sim 3.6 \times 10^9 \text{ J} \times 10^9 \text{ families/month} = 3.6 \times 10^{18} \text{ J/month}$

$$\rightarrow \frac{3.9 \times 10^{26} \text{J}}{3.6 \times 10^{18} \text{J}} = 1.1 \times 10^8 \text{ months} = 9.2 \times 10^6 \text{ years} \sim 10^7 \text{ years}$$

Atomic weight (원자량, 原子量) or relative atomic mass (상대 원자 질량):

$$H \rightarrow 1$$

12
C →12 (1.998467052×10⁻²³ g) (since 1962),

then H
$$\rightarrow$$
 1.0078
He \rightarrow 4.0026

 α -ray, α -particle : He nucleus

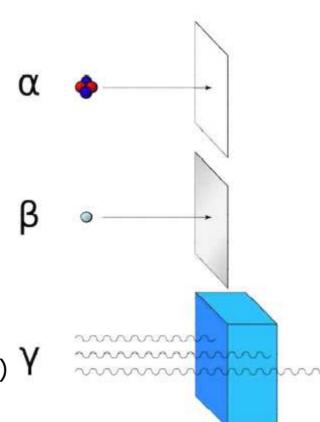

→ cannot penetrate a paper

 β -ray : electron

→ cannot penetrate aluminum

 γ -ray : high-energy photon

→ absorbed by dense materials (water, lead) Y

β(beta)-decay

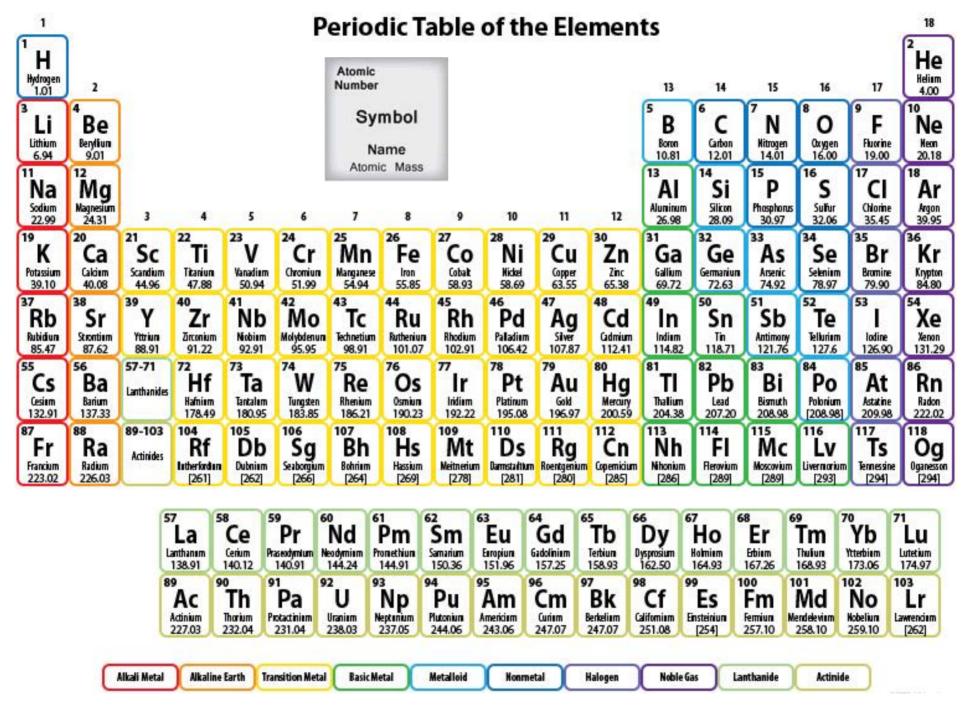

$$\beta$$
 decay : $n \rightarrow p + \beta + \overline{\nu_e}$

$$\beta^+$$
 decay : p \rightarrow n + β^+ + ν_e

$$\times \beta^- = e^-$$
 (electron)

$$\times \beta^+ = e^+$$
 (positron)

inverse-
$$\beta$$
 decay : $p^+ + e^- \rightarrow n + \nu$ (IBD)

Energy generation rate

H atomic weight: 1.0078
 4 H → 4.0312
 1 He → 4.0026
 △m = 0.0286

- $0.0286/4.0312 = 0.0071 \rightarrow 0.71\%$
- Only H in the core → T, P high enough to permit nuclear reactions → ~10 %
 of the mass of the Sun is available for energy conversion
- Thermonuclear energy available in the Sun :

$$L_{\odot} = 3.90 \times 10^{33} \text{ erg/s} = 3.90 \times 10^{26} \text{ J/s}$$

$$\rightarrow E/L_{\odot} = \text{Solar lifetime} = 8.11 \times 10^{9} \text{ yr } \sim 10 \text{ Gyr}$$

Energy generation rate

** AGN → efficiency of conversion from mass to energy ~10% (η=0.1)
 (see, e.g., Fabian & Rees 1995, MNRAS, 277, L55,
 http://phys.huji.ac.il/~joaw/winterschool/heckman_1.pdf)

** Gravitational wave (e.g, by merging of two identical black holes) → conversion efficiency ~30% (η~0.3)

(FBlack Hole Physics 1991, Edited by Venzo de Sabbata, Zhenjiu Zhang, NATO ASI Series, Vol. 364, p. 139)

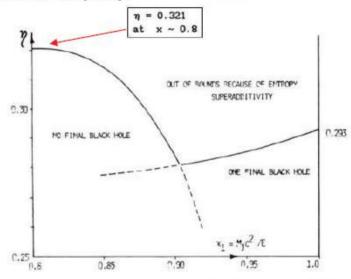

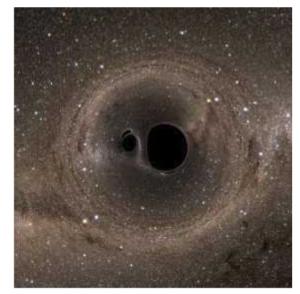

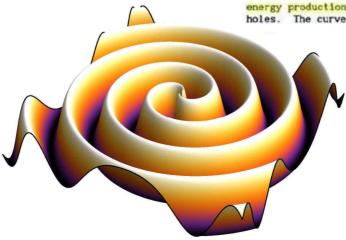

Figure 8. The maximum possible efficiency of gravitational wave energy production by the merging of two identical Schwarzschild black holes. The curves intersect at \times ~ 0.903, η ~ 0.281.

http://news.nationalgeographic.com/2016/02/1602 11-gravitational-waves-found-spacetime-science/

Energy generation rate

```
MS Lifetime : \tau=10<sup>10</sup>(M/L) yr (M=stellar mass, L=stellar luminosity) 

** Mass-Luminosity Relation : L/L_{\odot} = (M/M_{\odot})^{4} \quad \text{for M} > 0.4M_{\odot}
L/L_{\odot} = (M/M_{\odot})^{2.3} \quad \text{for M} < 0.4M_{\odot}
\to \tau = 10^{10} \, (M/M^{4}) \, \text{yr} = 10^{10} / \, [M(M_{\odot})]^{3} \, \text{yr}
1 \, M_{\odot} \to 10^{10} \, \text{yr}
10 \, M_{\odot} \to 10^{7} \, \text{yr}
```

O stars (the most massive stars) → a million years
"we are seeing some O stars!" = SF is still occurring in the MW

Main-sequence Lifetimes

http://www.ifa.Hawaii.edu/~szapudi/astro110/2007/ch21.pdf

Mass (M _☉)	Effective Temperature (K)	Spectral Class	Luminosity (L _o)	MS Lifetime (10 ⁶ yr)

0.50	4000	M	0.03	200,000

Proton-proton (PP) fusion chain process

```
1st step: {}^{1}H + {}^{1}H \rightarrow {}^{2}H + e^{+} + \nu_{e} (\rightarrow1.44 MeV)
               ^{1}H + ^{1}H \rightarrow ^{2}H + e^{+} + \nu_{e} \leftarrow \text{weak nuclear force}
                (It takes 5 \times 10^9 years for a given proton to undergo this reaction.)
2^{\text{nd}} step: {}^{2}\text{H} + {}^{1}\text{H} \rightarrow {}^{3}\text{He} + \gamma
                                                      (\rightarrow 5.49 \text{ MeV})
                                                               (occurs in \sim 1 s)
                ^{2}H + ^{1}H \rightarrow ^{3}He + \gamma
3^{rd} step: {}^{3}He + {}^{3}He \rightarrow {}^{4}He + {}^{1}H + {}^{1}H \quad (\rightarrow 12.9 \text{ MeV})
                                                               ← strong nuclear force
                                                              (It takes \sim 3 \times 10^5 years.)
 {}^{1}H = p : proton
 <sup>2</sup>H: deuterium (중수소) = p + n
 e+: positron (e-의 반물질 antimatter, same mass,
                                         positive charge)
 v: neutrino (energy, spin, very small mass)
   ν<sub>e</sub>: electron neutrino
 ^{3}He: helium-3 nucleus = 2p + 1n
 y: photon
 ^{4}He: helium-4 nucleus = ^{2}p + ^{2}n
 \rightarrow 91% of the time in the Sun
```

Proton-proton (PP) fusion chain process

$${}^{1}_{1}H + {}^{1}_{1}H \longrightarrow {}^{2}_{1}H + e^{+} + v_{e}$$

$${}^{2}_{1}H + {}^{1}_{1}H \longrightarrow {}^{3}_{2}He + \gamma$$

$${}^{69}_{69}$$

$${}^{31}_{60}$$

$${}^{3}_{2}He + {}^{3}_{2}He \longrightarrow {}^{4}_{2}He + 2{}^{1}_{1}H$$

$${}^{3}_{2}He + {}^{4}_{2}He \longrightarrow {}^{7}_{4}Be + \gamma$$

$${}^{(PP I)}$$

$${}^{99.7}_{60}$$

$${}^{7}_{4}Be + e^{-} \longrightarrow {}^{7}_{3}Li + v_{e}$$

$${}^{7}_{4}Be + {}^{1}_{1}H \longrightarrow {}^{8}_{5}B + \gamma$$

$${}^{7}_{3}Li + {}^{1}_{1}H \longrightarrow {}^{2}_{2}He$$

$${}^{8}_{4}Be \longrightarrow {}^{8}_{4}Be + e^{+} + v_{e}$$

$${}^{8}_{4}Be \longrightarrow {}^{2}_{2}He$$

$${}^{8}_{4}Be \longrightarrow {}^{2}_{2}He$$

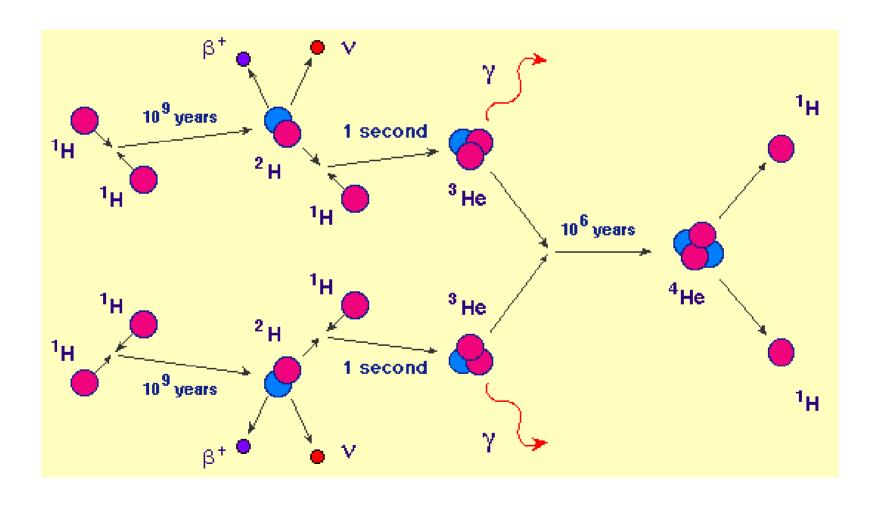

$${}^{99.11}_{(Lithium burning)}$$

$${}^{(PP III)}_{(Lithium burning)}$$

$${}^{(PP III)}_{(PP III)}$$

Why this complicated process?

- Direct collision of 4 H atoms to produce He → probability is very low
- Relatively, 2-body collision is more often!

proton-proton (PP) fusion chain process

Proton-proton fusion chain process

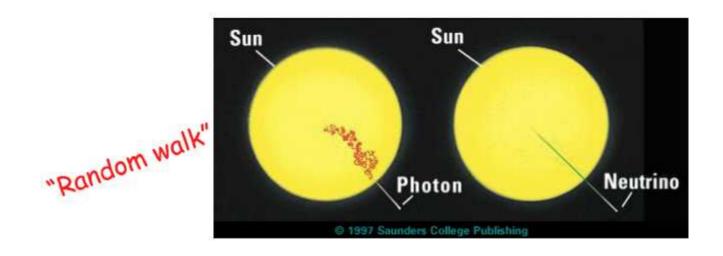

1st step: In two separate reactions, 2 protons in each reaction fuse

- 1st step : $p + p -> \beta^+ + \nu + {}^2H$
- 2^{nd} step : ${}^{2}H + p --> {}^{3}He + \gamma$
- 3^{rd} step: 3 He + 3 He --> 4 He + p + p

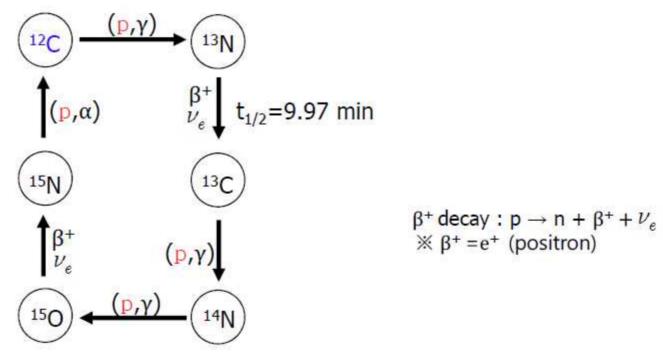

Photon, neutrino – escape from the Sun

Photon and neutrino – travel times out of the center of the Sun 10^4 - 10^5 yr 2 sec

CNO Cycle

- Carbon = catalyst : a substance that causes a chemical reaction to happen more quickly, while the substance not consumed and remain unchanged
- 촉매(觸媒): 반응과정에서 소모되거나 변화되지 않으면서 반응속도를
 빠르거나 느리게 변화시키는 물질

- Start : C + p
- At high-temp stars : T > 1.6 \times 10⁷ K, M > 1.1 M $_{\odot}$

CNO cycle process

$$^{12}\text{C} + ^{1}\text{H} \rightarrow ^{13}\text{N} + \gamma$$

$$^{13}N \rightarrow ^{13}C + e^+ + \nu_e$$
 ^{13}N : unstable isotope

$$^{13}\text{C} + ^{1}\text{H} \rightarrow ^{14}\text{N} + \gamma$$

$$^{14}N + ^{1}H \rightarrow ^{15}O + \gamma$$

$$^{15}O \rightarrow ^{15}N + e^{+} + \nu_{e}$$

 $^{15}O \rightarrow ^{15}N + e^+ + \nu_e$ ^{15}O : unstable isotope

$$^{15}N + ^{1}H \rightarrow ^{12}C + ^{4}He$$

CNO cycle process

$$^{12}\text{C} + ^{1}\text{H} \rightarrow ^{13}\text{N} + \gamma$$
 (1.95 MeV)

$$^{13}N \rightarrow ^{13}C + e^{+} + \nu_{e}$$
 (1.20 MeV, ^{13}N half-life=9.965^m)

$$^{13}\text{C} + ^{1}\text{H} \rightarrow ^{14}\text{N} + \gamma$$
 (7.54 MeV)

$$^{14}N + ^{1}H \rightarrow ^{15}O + \gamma$$
 (7.35 MeV)

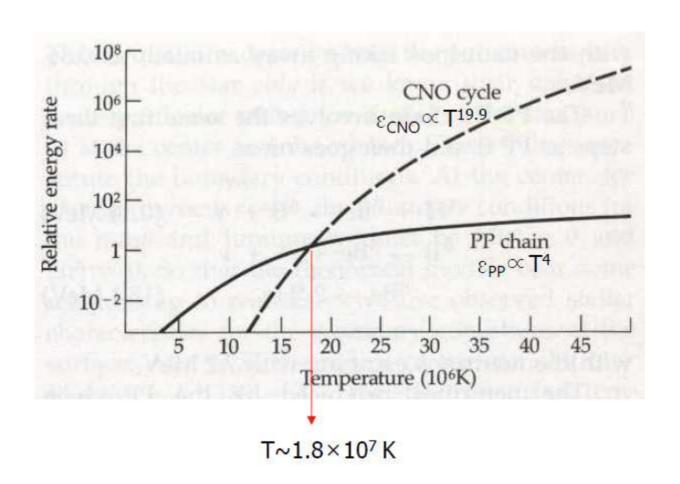

$$^{15}\text{O} \rightarrow ^{15}\text{N} + \text{e}^+ + \nu_{\text{e}}$$
 (1.73 MeV, ^{15}O half-life=122.24s)

$$^{15}N + ^{1}H \rightarrow ^{12}C + ^{4}He$$
 (4.96 MeV)

※ 2 positrons annihilate with 2 ambient electrons → produce 2.04 MeV

Total 24.73 + 2.04 = 26.73 MeV

Energy-generation rates

Triple-alpha (3α) process

Nucleosynthesis using He: T \geq 10⁸ K, $\rho \geq$ 10⁵ g cm⁻³ : He \rightarrow heavier elements $^{4}\text{He} + ^{4}\text{He} \Leftrightarrow ^{8}\text{Be} + \gamma$ (-0.0918 MeV) * 8Be lifetime $\sim 2.6 \times 10^{-16}$ s > mean collision (scattering) time of α -particle ($T_{\text{scattering}}$) Huge amount of He, $n(^{8}Be)$: $n(^{4}He) = 1 : 10^{9}$ ${}^{8}\text{Be} + {}^{4}\text{He} \rightarrow {}^{12}\text{C} + \gamma$ (+7.367 MeV) \langle Emitted energy \rangle = +7.275 MeV ⁴He/ "Triple- α process" Proton

$$\rightarrow ^{31}\text{P} + \text{p} \quad (7.678 \text{ MeV}) \ (\sim 40\%)$$

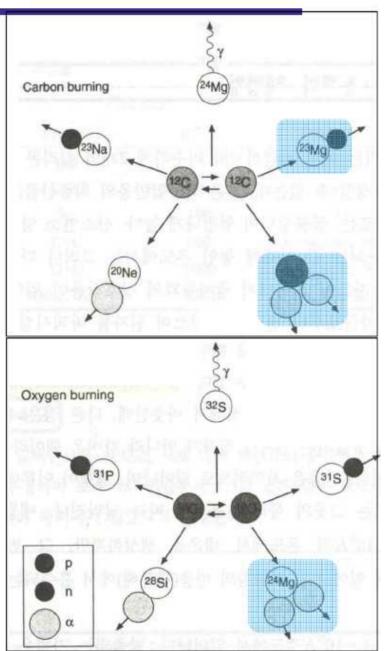

$$\rightarrow ^{31}\text{S} + \text{n} \quad (1.500 \text{ MeV})$$

$$\rightarrow ^{32}\text{S} + \gamma$$

$$\rightarrow ^{24}\text{Mg} + 2\alpha \quad \text{(endothermic)}$$

$$^{\langle \text{Emitted energy} \rangle} \approx 16 \text{ MeV}$$

$$^{\sim 4.8 \times 10^{13} \text{ J/kg}} = 4.8 \times 10^{17} \text{ erg/g}$$

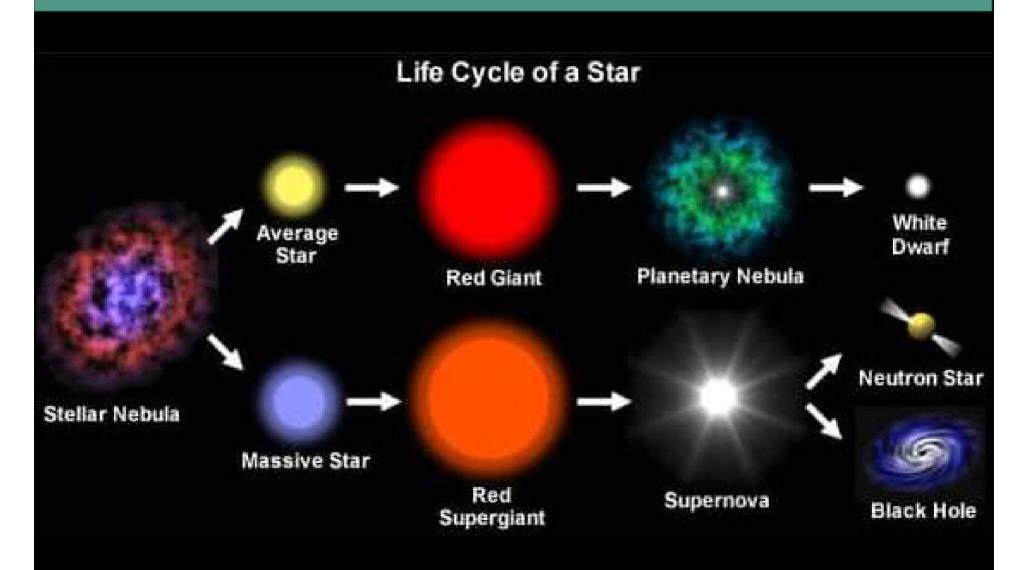

Si-burning

- After O-burning, core = Si + S
- T ~ $(2.7-3.5) \times 10^9$ K (depends on mass)
- Duration ~ 2 weeks
- No further fusion is possible.

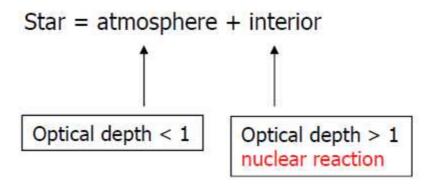

$$^{28}_{14}\text{Si}$$
 + $^{4}_{2}\text{He}$ \rightarrow $^{32}_{16}\text{S}$
 $^{32}_{16}\text{S}$ + $^{4}_{2}\text{He}$ \rightarrow $^{36}_{18}\text{Ar}$
 $^{36}_{18}\text{Ar}$ + $^{4}_{2}\text{He}$ \rightarrow $^{40}_{20}\text{Ca}$
 $^{40}_{20}\text{Ca}$ + $^{4}_{2}\text{He}$ \rightarrow $^{44}_{22}\text{Ti}$
 $^{44}_{22}\text{Ti}$ + $^{4}_{2}\text{He}$ \rightarrow $^{48}_{24}\text{Cr}$
 $^{48}_{24}\text{Cr}$ + $^{4}_{2}\text{He}$ \rightarrow $^{52}_{26}\text{Fe}$
 $^{52}_{26}\text{Fe}$ + $^{4}_{2}\text{He}$ \rightarrow $^{56}_{28}\text{Nii}$

2. The Evolution of Stars (별의 진화) 2-2 Stellar Evolution (항성 진화)

Sun + Star

Solar surface composition: X=0.73, Y=0.25, Z=0.02

 $\,$ % Optical depth, $\, au_{\lambda} \, : \, \, d au_{\lambda} = \, - \, \kappa_{\lambda} \, \rho \, d s \,$

 $au_{\lambda}\gg 1$: optically thick

 $au_{\lambda} \ll 1$: optically thin

ptically thin $imes \kappa_\lambda$: absorption coefficient (opacity)

Sun's interior

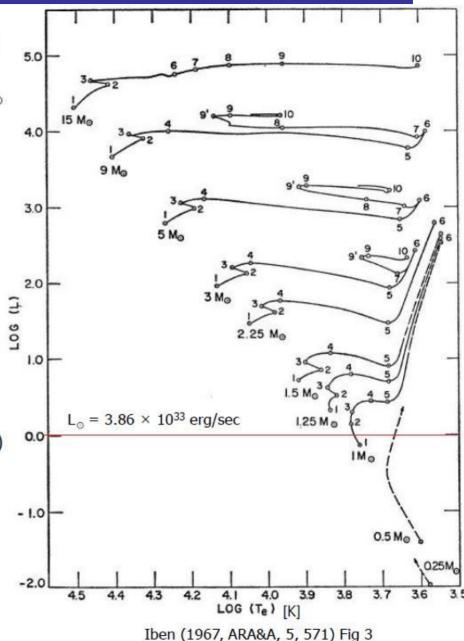

Post-MS Stellar Evolution

Hertzsprung-Russell Diagram of Metal-rich stars (X=0.708, Y=0.272, Z=0.020)

 $M = 15, 9, 5, 3, 2.25, 1.5, 1.25, 1, 0.5, 0.25 M_{\odot}$

Dashed lines: estimates

• Sun's L, R, T: increased steadily since it reached the zero-age main sequence (ZAMS) ~4.5 Gyr ago

Solar Evolution

Sun's center, during its lifetime :

 $X: 0.71 \rightarrow 0.34$ $Y: 0.27 \rightarrow 0.64$

changing the composition and structure

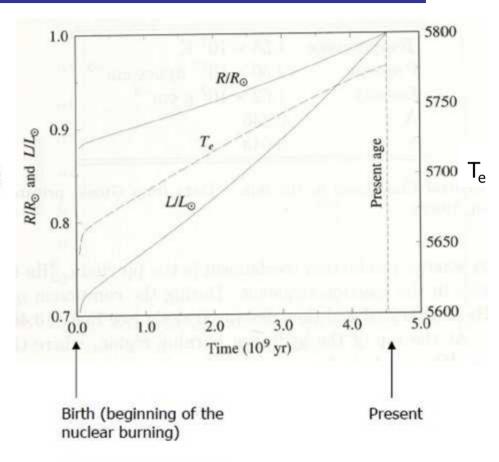

The change in the Sun's central composition
→direct influence on observable L, T_{eff}, and R

L increased by 40%
R increased by > 10%

※ Physical parameters of the Solar center (standard solar model of Joyce Guzik)

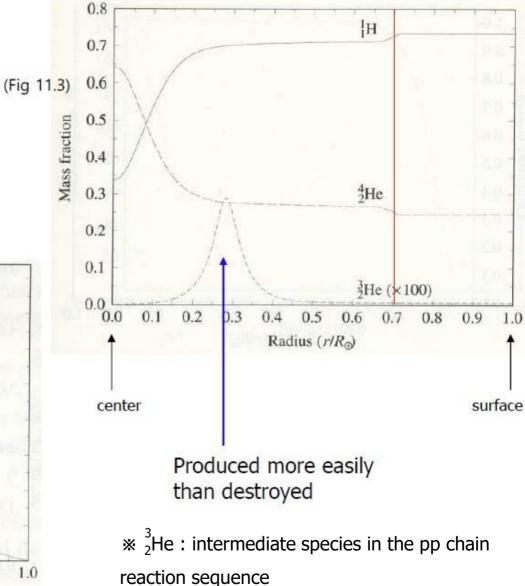

Central conditions in the Sun

Tc	(1.56~) 1.58 ×10 ⁷ K
P _C	2.50×10 ¹⁷ dyne/cm ²
ρ_{C}	162 (150-160) g/cm ³
X_{C}	0.336
Yc	0.643

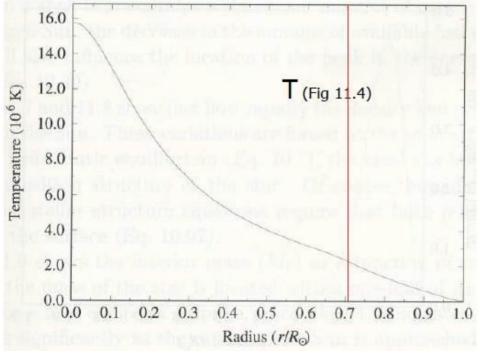

L: 1.43 times increase

Solar composition structure

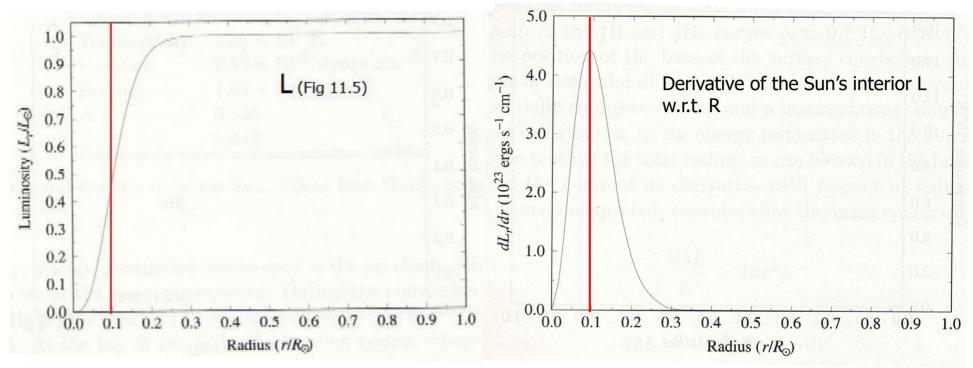

Solar Temp structure

Interior Lum of the Sun

Location of the greatest contribution to the E output

Though amount of E liberated per gram of material (ε) decreases steadily from R=0 outward

→ Largest contribution to the total L – in a shell that contains a significant amount of mass

Post-MS Stellar Evolution

Numbers in parentheses beside each entry give the power of ten to which that entry is to be raised.

TABLE IV STELLAR LIFETIMES (yr)*

Interval (i-j) Mass (Mo)	(6–7)	(7–8)	(8-9)	(9–10)
15	7.17 (5)	6.20 (5)	1.9 (5)	3.5 (4)
9	4.90 (5)	9.50 (4)	3.28 (6)	1.55 (5)
5	6.05 (6)	1.02 (6)	9.00 (6)	9.30 (5)
3	2.51 (7)	4.08	3 (7)	6.00 (6)

Numbers in parentheses beside each entry give the power of ten to which that entry is to be raised.

2. The Evolution of Stars (별의 진화) 2-3 Post-Main-Sequence Evolution (주계열 이후 진화)

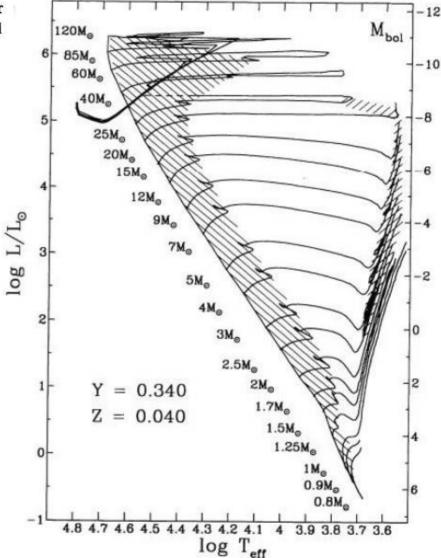

D. Schaerer, C. Charbonnel, G. Meynet, A. Maeder and G. Schaller Geneva Observatory, CH-1290 Sauverny, Switzerland 1993 Astron. Astrophys. Suppl. Ser. 102, 339

Grids of stellar models.

IV. From 0.8 to 120 M_{\odot} at Z = 0.040

Stellar evolution isochrones

- Padova (Bressan+12 MN 427 127)
- Geneva
- VandenBerg (83 ApJS 51 29)
- Yonsei-Yale (Y²) (Demarque+04 ApJS 155 667)
- Dartmouth (Dotter+07 ApJ 666 403)
- Modules for Experiments in Stellar Astrophysics (MESA) (Paxton+11 ApJS 192 3)
- MESA Isochrones and Stellar Tracks (MIST) (Dotter 16 ApJS 222 8)
- Yunnan-III (Zhang+13 MN 428 3390)

Schaerer et al (1993, A&AS, 102, 339) - Fig 1

Hatched areas: slow phases of nuclear burning

D. Schaerer, C. Charbonnel, G. Meynet, A. Maeder and G. Schaller
 Geneva Observatory, CH-1290 Sauverny, Switzerland
 1993 Astron. Astrophys. Suppl. Ser. 102, 339

Grids of stellar models.

IV. From 0.8 to 120 M_{\odot} at Z = 0.040

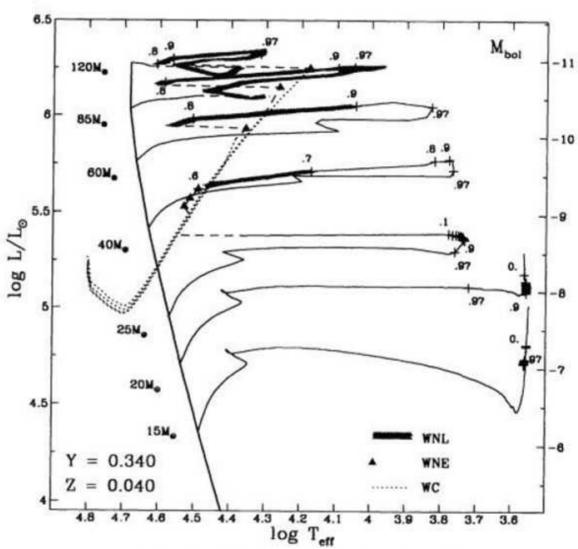

HRD of massive stars (15 – 120 M_{\odot}) with Z=0.040

Yc (central He content): 0.97, 0.90, 0.80, 0.70, 0.60, ---, 0.10, 0

Wolf-Rayet stars

- Hot : $T_{\text{eff}} = 30,000 200,000 \text{ K}$
- Broad emission lines of He I, He II, C III, C IV, N III, N V
- Very high surface enhancement of heavy elements (He etc.), depletion of hydrogen
- Strong stellar winds

WN Early (WN2 – WN6) WN Late (WN6 – WN9) WC

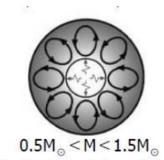

Schaerer et al (1993, A&AS, 102, 339) - Fig 3

Characteristics of MS Stars

M > 1.5 M _☉	M <1.5 M _☉
$T_c > 2 \times 10^7 \text{ K}$	$T_c < 2 \times 10^7 \text{ K}$
CNO cycle	PP chain
Energy production rate : $\epsilon_{CNO} \propto T^{19.9}$ > Production of most E near the center	$\epsilon_{CNO} \propto T^4$ > E source is not concentrated to the center
core : convective	core : radiative
envelope : radiation	envelope : H-convection
The more massive, the larger convective core.	As mass decreases, H-convection zone deepens.

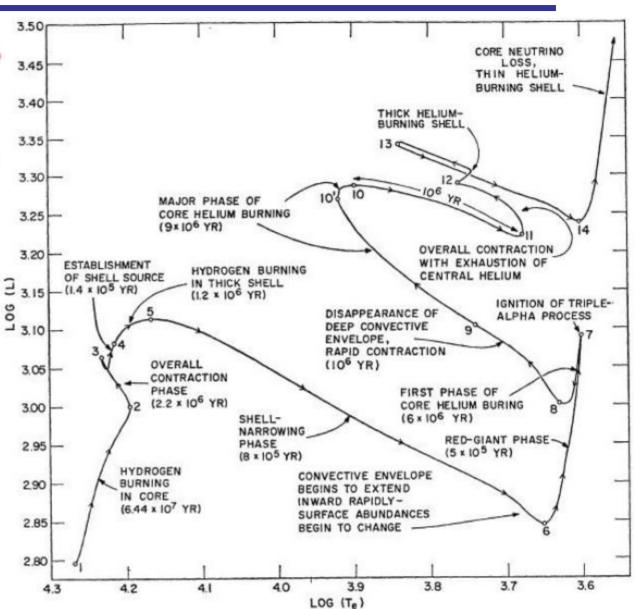

M<0.5M

https://ase.tufts.edu/cosmos/view_picture.asp?id=1409

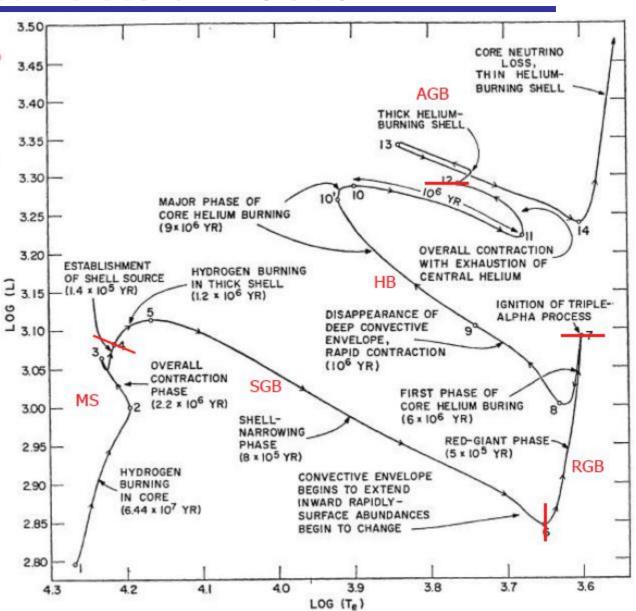

Dominant energy transport mode :

- Low temperature gradient, low opacity → radiation
- Steep temperature gradient → convection

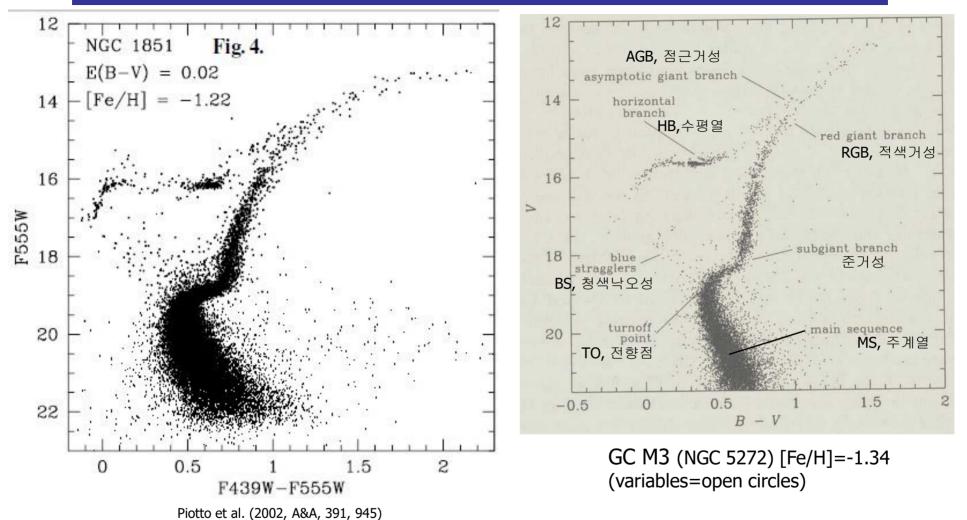

- Evolutionary path of a 5 M_o metal-rich star in the HRD
- From ZAMS
 to the asymptotic giant branch
 (AGB)

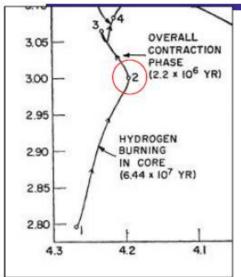

- Evolutionary path of a 5 M_o metal-rich star in the HRD
- From ZAMS
 to the asymptotic giant branch
 (AGB)

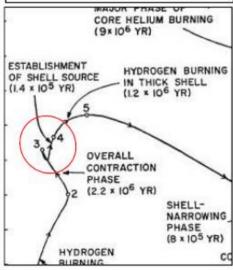

Color-Magnitude Diagrams for globular clusters (GCs)

5 M_o star - structure

- At point 2: near depletion of H fuel in the core
- During 2 → 3 : overall contraction (Core H mass fraction X : reduced to 0.01)

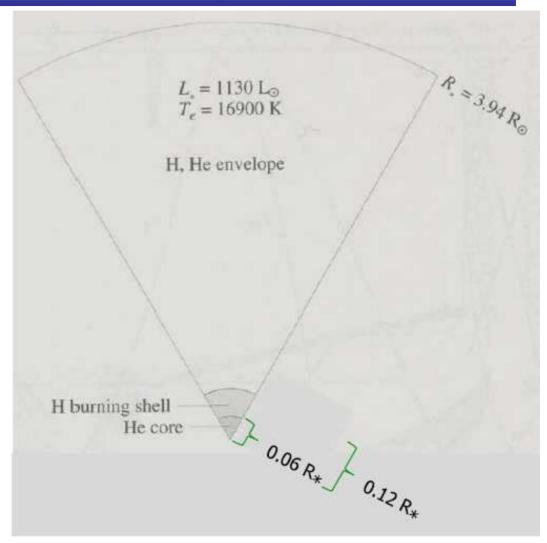

- During 3 → 4 : establishment of shell source H burning begins in a thick shell
- Rapid shell ignition → overlying envelope absorbs some or much of the E release by the shell → envelope slightly expands

5 M_☉ star approaching the RGB

Shortly after point 3

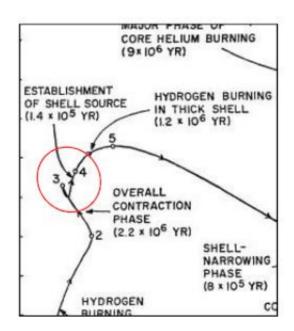

H shell burning

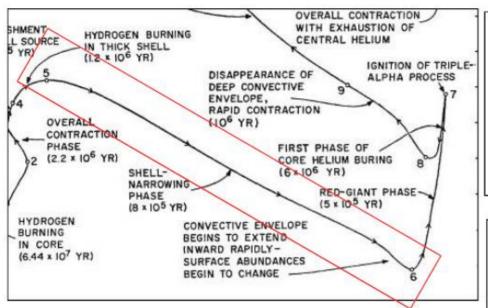

An Introduction to Modern Astrophysics (2nd edition), Bradley W. Carroll & Dale A. Ostlie (1996), p. 498

Evolution beyond point 3

- Generated energy → goes into slow expansion of the envelope
- T_{eff} decreases slightly, evolutionary track bens to the right
- Redward locus = subgiant branch

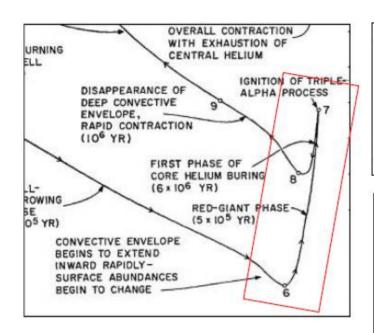

Sub Giant Branch (SGB): 5 M_☉ star

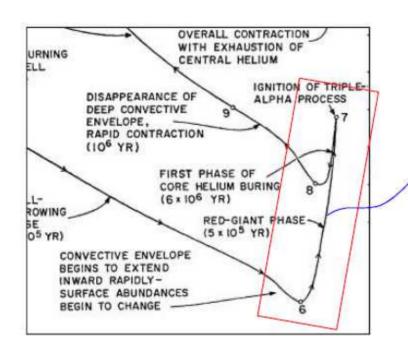

- During point 5 → 6 :
 - Envelope expands (absorbing much of the shell's E, before it reaches the surface)
- → L decreases, effective T decreases, photospheric optacity increases (H⁻ ion)
- convection zone begins to develop near the surface
- Base of the convection zone → extends down into regions where the chemical composition has been modified by nuclear processes
- Surface convection zone encounters these chemically modified regions
- → Processed material become mixed
- \rightarrow Photosphere composition change (Li \downarrow , ${}_{2}^{3}$ He \uparrow)
- "First dredge-up" begins at point 6

5 M_o star at the RGB

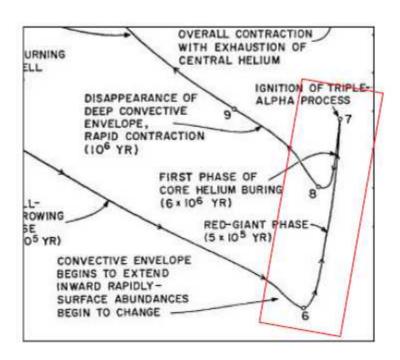

- During 6 → 7
 - : core continues to contract degenerate He
- → (narrowing) H-b shell E-production rate ↑
- \rightarrow L1, R1
- → vertical evolution, "red giant branch (RGB)"
- At point 7 :
- $-T_c=1.3\times10^8 \text{ K}$
- $-\rho_c = 7700 \text{ g/cm}^3$
- High central T and density → quantum-mechanical tunneling through the Coulomb barrier (acting between ⁴He nuclei) becomes effective
 - \rightarrow triple- α process begins
- Slow ignition of He-burning phase!
- New source of E → core expands
- → Shell E-generation rate decreases
- $\rightarrow L \downarrow$
 - and envelope contracts, T_{eff}↑

※ For low mass stars of M < 2 M_☉

- As He-core continues to collapse
- → Core becomes strongly electron-degenerate
- T, ρ become high enough to initiate the triple- α process (10⁸ K, 10⁴ g/cm³)
- → Explosive E release! (core) helium flash
- Luminosity ~10¹¹ L_o
- → For only a few seconds!
 (most of the E never reaches the surface)
- → E "lifts" the degeneracy and absorbed by the overlying layers of the envelope (possibly cause some mass loss)

※ For low mass stars of M < 2 M_☉

(core) helium flash

: Nearly constant mass – function of metallicity $\sim 1.6~{\rm M}_{\odot}$ for population I stars

 $\sim 1~{\rm M}_{\odot}$ for population II stars

For pop II stars (ages 2-15 Gyr),
 if metallicity is same

→ bolometric luminosity is ~ constant (varies only by ~ 0.1 mag)

→ TRGB (tip of the red giant branch)
: distance indicator for old, resolved galaxies

TRGB (tip of the red giant branch)
